# The Nobel Prize in Physics 1994

Neutrons behave as particles and as waves

Clifford G. Shull, MIT, Cambridge, Massachusetts, USA, receives one half of the 1994 Nobel Prize in Physics for development of the neutron diffraction technique.

The Royal Swedish Academy of Sciences has awarded the 1994 Nobel Prize in Physics for pioneering contributions to the development of neutron scattering techniques for studies of condensed matter.

Bertram N. Brockhouse, McMaster University, Hamilton, Ontario, Canada, receives one half of the 1994 Nobel Prize in Physics for the development of neutron spectroscopy.

**S**hull made use of elastic scattering i.e. of neutrons which change direction without losing energy when they collide with atoms.

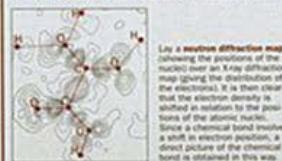

Because of the wave nature of neutrons, a diffraction pattern can be recorded which indicates where in the sample the atoms are situated. Even the placing of light elements such as hydrogen in metallic hydrides, or hydrogen, carbon and oxygen in organic substances can be determined.

The pattern also shows how atomic dipoles are oriented in magnetic materials, since neutrons are affected by magnetic forces. Shull also made use of this phenomenon in his neutron diffraction technique.

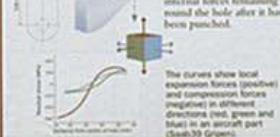

An early (1950s) neutron diffractometer with neutron wavelength control here used by E.D. Wilsen and C.G. Shull (standing) at Oak Ridge National Laboratory.

**Neutrons see more than X-rays**  
X-rays are scattered by electrons, neutrons by atomic nuclei. With X-rays it is easiest to see atoms that have many electrons. Hydrogen, for example, which has only one electron, is not so easy to see. With neutrons, all kinds of atoms are visible.

**Neutrons reveal inner stresses**  
A hole has been punched in an important metal aircraft part. Does the part match up? Neutron diffraction can show how much the distances between atoms has changed and hence the internal forces remaining round the hole after it has been punched.

**Neutrons show what atoms remember**  
of their earlier positions when they move randomly in relation to each other in liquids and solids. Even here there is in fact some local order. The atoms cannot move infinitely close to each other. Some distances are more common than others.

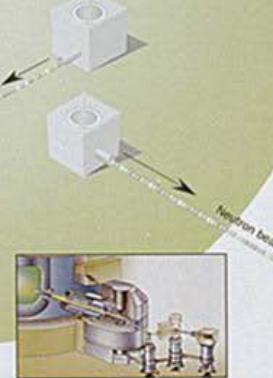

## Neutrons reveal structure and dynamics

### Neutrons show where atoms are

When the neutrons collide with atoms in the sample material, they change direction (are scattered) – elastic scattering.  
Atoms in a crystalline sample  
Detectors record the directions of the neutrons and a diffraction pattern is obtained.  
The pattern shows the positions of the atoms relative to one another.

Neutrons bounce against atomic nuclei. They also react to the magnetism of the atoms.

### Research reactor

### Neutrons show what atoms do

3-axis spectrometer with rotatable crystals and rotatable sample  
Atoms in a crystalline sample  
Changes in the energy of the neutrons are first analysed in an analyser crystal...  
...and the neutrons then counted in a detector.

When the neutrons penetrate the sample they start or cancel oscillations in the atoms. If the neutrons create phonons or magnons themselves lose the energy these absorb – inelastic scattering

**How it started**  
Brockhouse and Shull made their pioneering contributions at the first nuclear reactors in the USA and Canada back in the 1940s and 1950s. It was then that the resources of the reactors became available for peacetime research.

### ... how it continues

Thousands of researchers are now working at the many neutron research centres throughout the world. New and very advanced neutron scattering installations have been built and more are planned in Europe, the USA and Asia. At these super-installations the researchers are studying the structure of new ceramic superconductors, molecular movements on surfaces of interest for catalytic exhaust cleaning, virus structures and the connection between the structure and the elastic properties of polymers.

**B**rockhouse made use of inelastic scattering i.e. of neutrons, which change both direction and energy when they collide with atoms. They then start or cancel atomic oscillations in crystals and record movements in liquids and melts. Neutrons can also interact with spin waves in magnets.

With his 3-axis spectrometer Brockhouse measured energies of phonons (atomic vibrations) and magnons (magnetic waves). He also studied how atomic structures in liquids change with time.

(Received March 2, 1951)

$$u(r) = (2r/\pi) \int_0^{\infty} kf(k) \sin kr dk$$

$$d\sigma_m = \frac{2}{3} S(S+1) (e^2 \gamma / mc^2) f^2 d\Omega,$$

(a) The magnetic moments are aligned along arbitrary [100] directions, in other words, along the cube axes, as illustrated in Fig. 5. For this case it can be shown that  $q^2$  (average) =  $\frac{2}{3}$  for each of the four observed magnetic reflections in MnO.

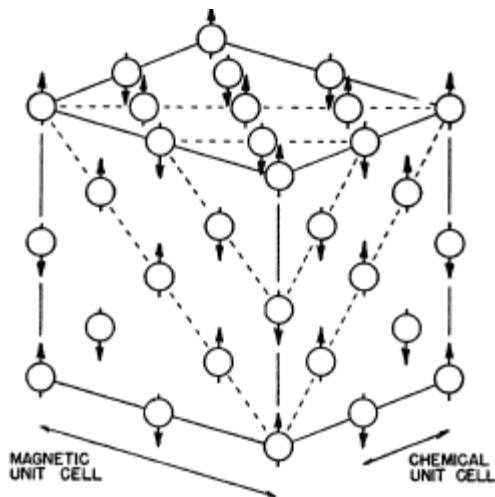

(b) The magnetic moments are aligned perpendicular to the ferromagnetic (111) sheets. For this case,  $q^2$  vanishes for the (111) reflection and becomes 32/33 for the (311) and 32/57 for the (331) reflections.

(c) The magnetic moments are aligned arbitrarily in the ferromagnetic (111) sheets. Here  $q^2$  should be 1 for the (111) reflection and various odd values for the other reflections, depending upon the assignment of moment orientation within the sheet.

TABLE II. Comparison between observed MnO antiferromagnetic intensities and those calculated for various models of magnetic orientation with respect to crystallographic axes.

	Calculated for various oriented models			Observed (neutrons/min)
	(a)	(b)	(c)	
(111)	1038	0	1560	1072
(311)	460	675	...	308
(331)	129	109	...	132
(511) (333)	54	24	...	70

## Xtal+more representation analysis

# Powder Diffraction

## Advantages

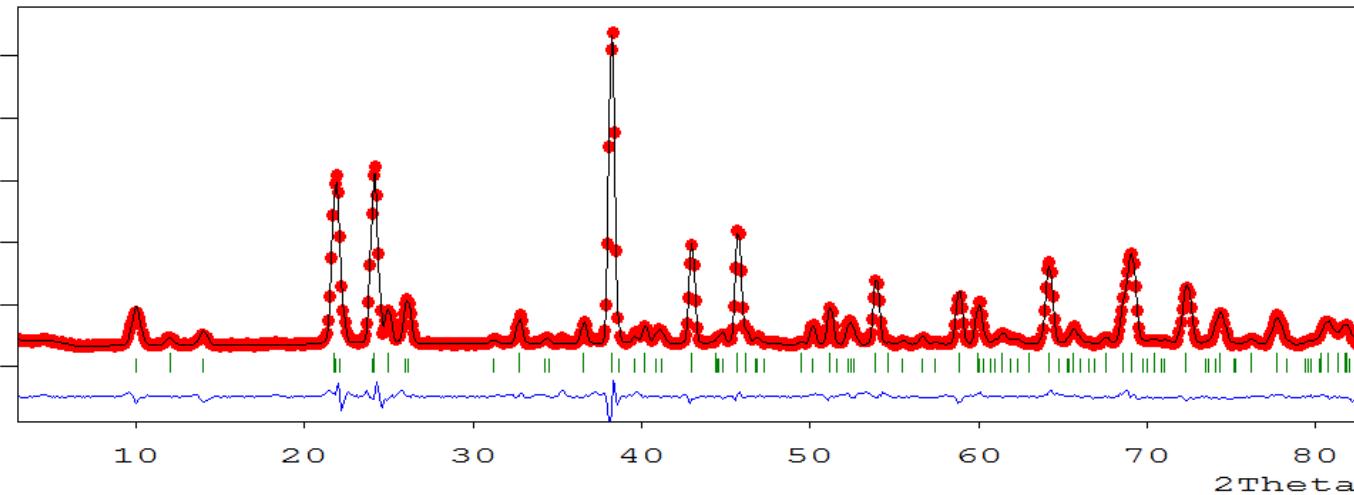

- You get the big picture
- Can get the propagation vector
- Avoids the muss and fuss of extinction
- It's often Good Enough™

## Disadvantages

- Can be hard to truly index  $\mathbf{k}$ —is it  $[3\ 4\ 0]$  or  $[0\ 0\ 5]$ ?
- You average over all symmetry equivalent  $\mathbf{k}$  at any particular Bragg angle
- You lose information in the powder averaging
- No domain info
- No multi- $\mathbf{k}$  info
- Can be very hard to determine phase

Cycle: 2 Chi2: 18.2 dy.dat

Intensity (arb. units)

- Determine the propagation vector
- Use symmetry analysis to constrain the possible magnetic structures
- Refine the moment directions and magnitudes

# Single Crystal Diffraction

## Advantages

- Can fully determine  $\mathbf{k}$
- Can investigate domain populations
- Can apply probes (magnetic field, E-field, pressure, etc.) along a particular direction to see effect on magnetic ordering

## Disadvantages

- Extinction
- Absorption depends on shape
- Reciprocal space is large...
- Crystal growth is hard...
