High Energy X-rays?

Loose definition ⇨

Photons between 40 - 120 keV

Why?

Low Absorption

Bulk measurements

Special environments

Furnaces

Reaction cells

Cryostats

High-pressure cells

Often comparable to neutrons

Simplified Scattering

Kinematical diffraction

Small absorption, polarization, & dispersion corrections

Small Diffraction Angles

Large Q range

Forward scattering

What?

Stress/strain/texture measurements

Small-angle scattering

High energy diffraction microscopy (HEDM)

(i.e., grain tracking)

Pair distribution functions (PDF)

Includes high-pressure

Powder diffraction

High-resolution (point counting)

Time-resolved (area detectors)

Diffuse scattering

Triple-axis diffractometry

Fluorescence measurements

Imaging

Tomography

Radiography

Combinations of the above

SAXS/WAXS

Imaging/WAXS

X-ray Absorption

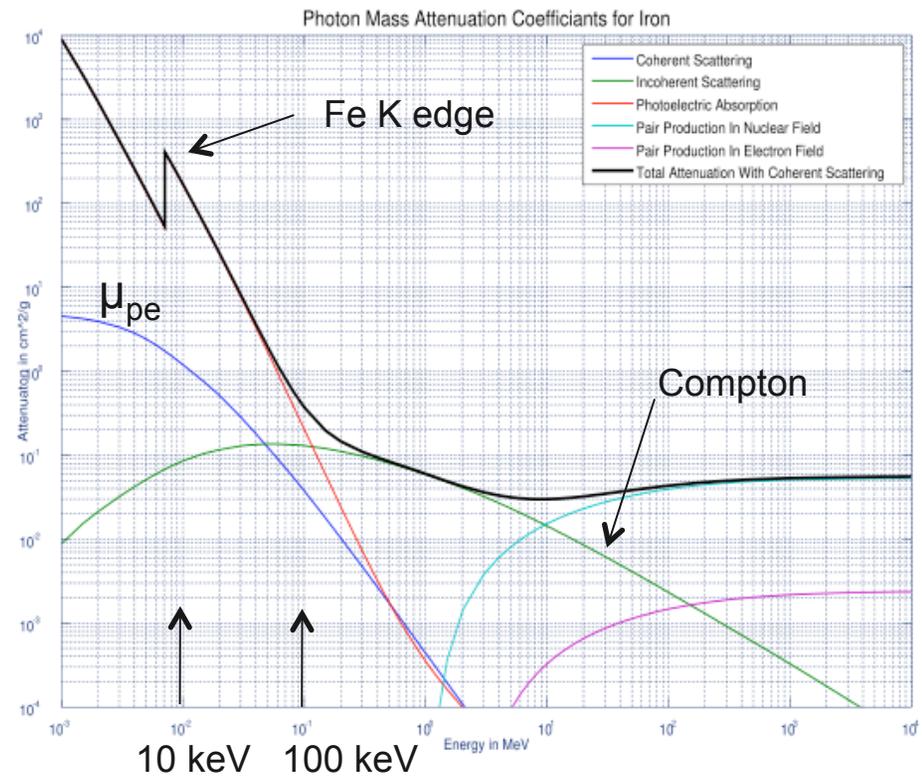

$$I_x = I_o e^{-(\mu/\rho)\rho x}$$

- I_o original beam intensity
- I_x measured beam intensity
- μ/ρ mass absorption coeff.
- ρ material density
- x material thickness

$$\mu_{pe} \sim Z^3 / E^3$$

Note: Compton scattering becomes increasing more important as Z decreases and E increase.

Photon Mass Absorption for Fe

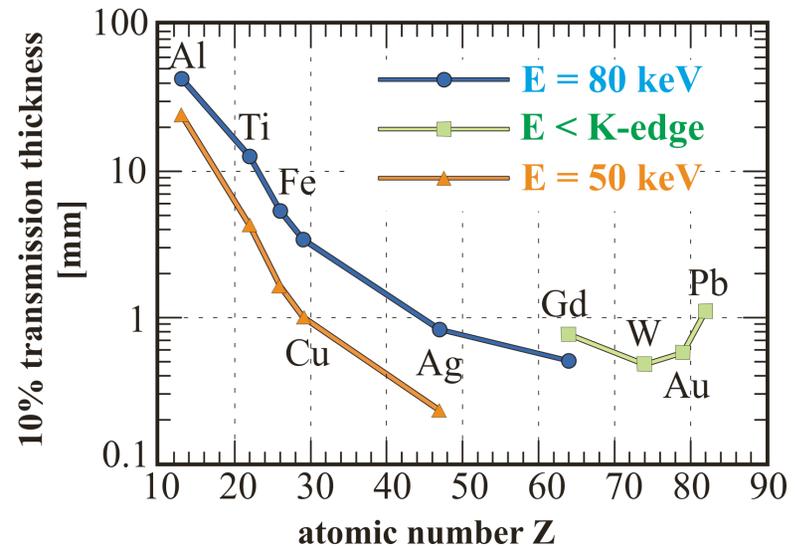

Graph from wikipedia

X-ray Absorption at High Energies

Low Absorption

- Bulk measurements
- Smaller absorption corrections to data
- Special environments
 - Furnaces*
 - Reaction cells*
 - Cryostats*
 - High-pressure cells*

Often comparable to neutrons

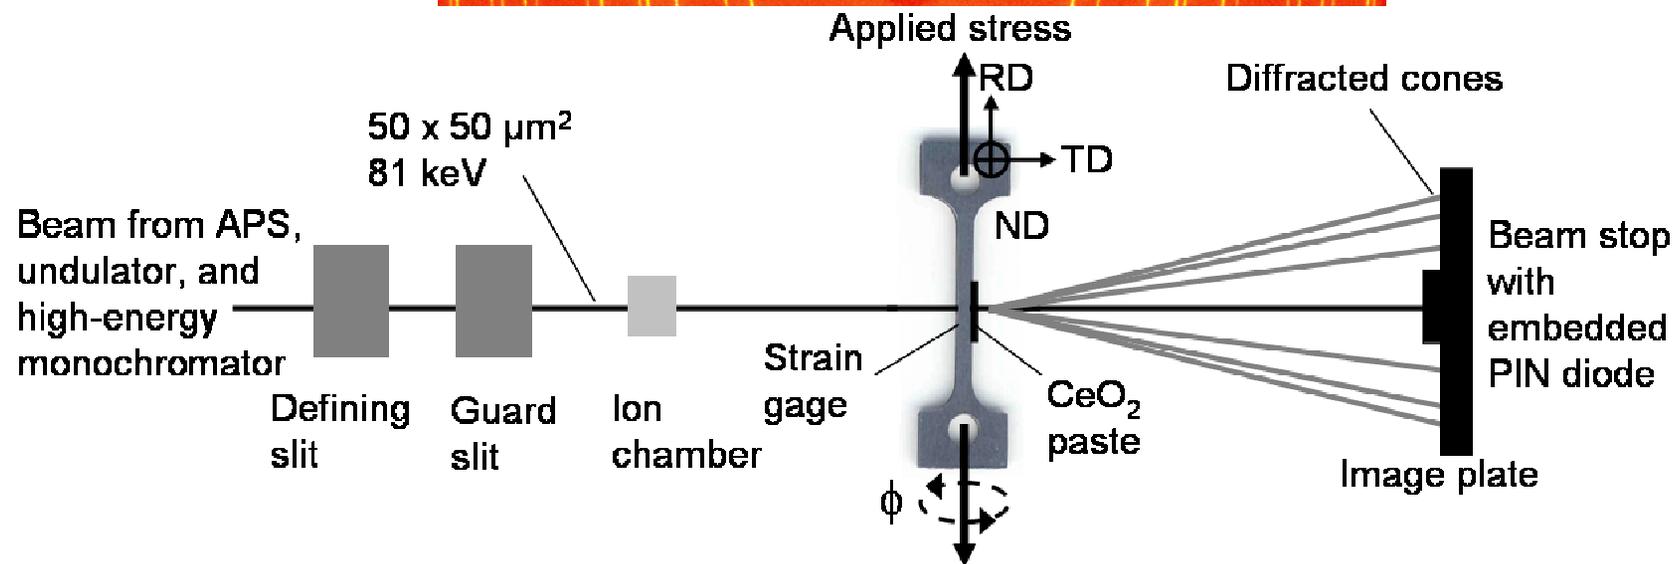

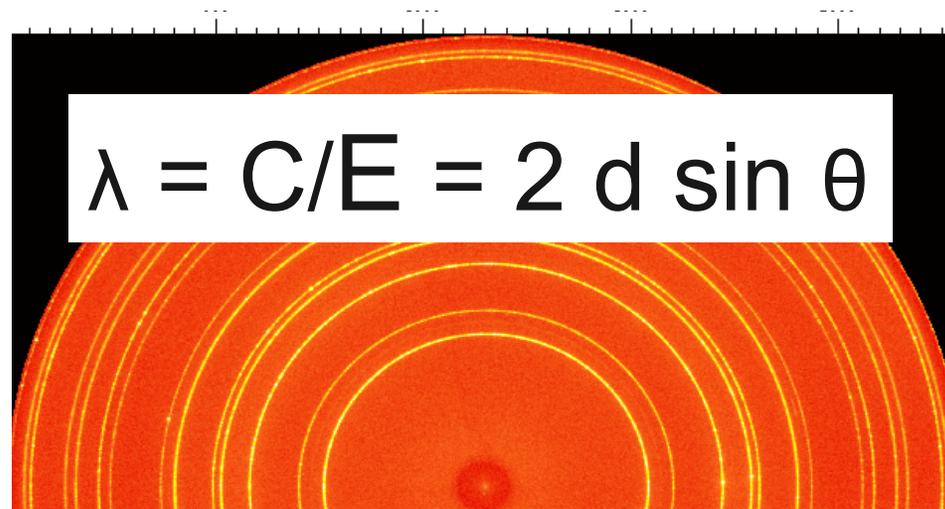

X-ray Penetration Distances in Selected Metals

Material	Mo tube 17.48 keV	Synchrotron, 80 keV
Copper	0.10 mm	6.9 mm
Bronze (10%Sn)	0.11 mm	5.5 mm
Brass (25%Zn)	0.11 mm	7.1 mm
Wrought Iron (0.01 % C)	0.16 mm	10.7 mm
Cast Iron (3 % C)	0.17 mm	11.2 mm

Simplified Scattering

- More kinematical scattering
 - Extinction length $\sim E$
 - Dynamical scattering $I \sim |F|$
 - Kinematical scattering $I \sim |F|^2$
 - In between is a problem
 - *Primary/secondary extinction*
- Smaller diffraction angles lead to smaller polarization effects
- For all but heavy elements, well above the K-edges
 - Cerium K-edge at 40.44 keV
 - Negligible anomalous scattering effects for most cases

Forward Scattering/High Q

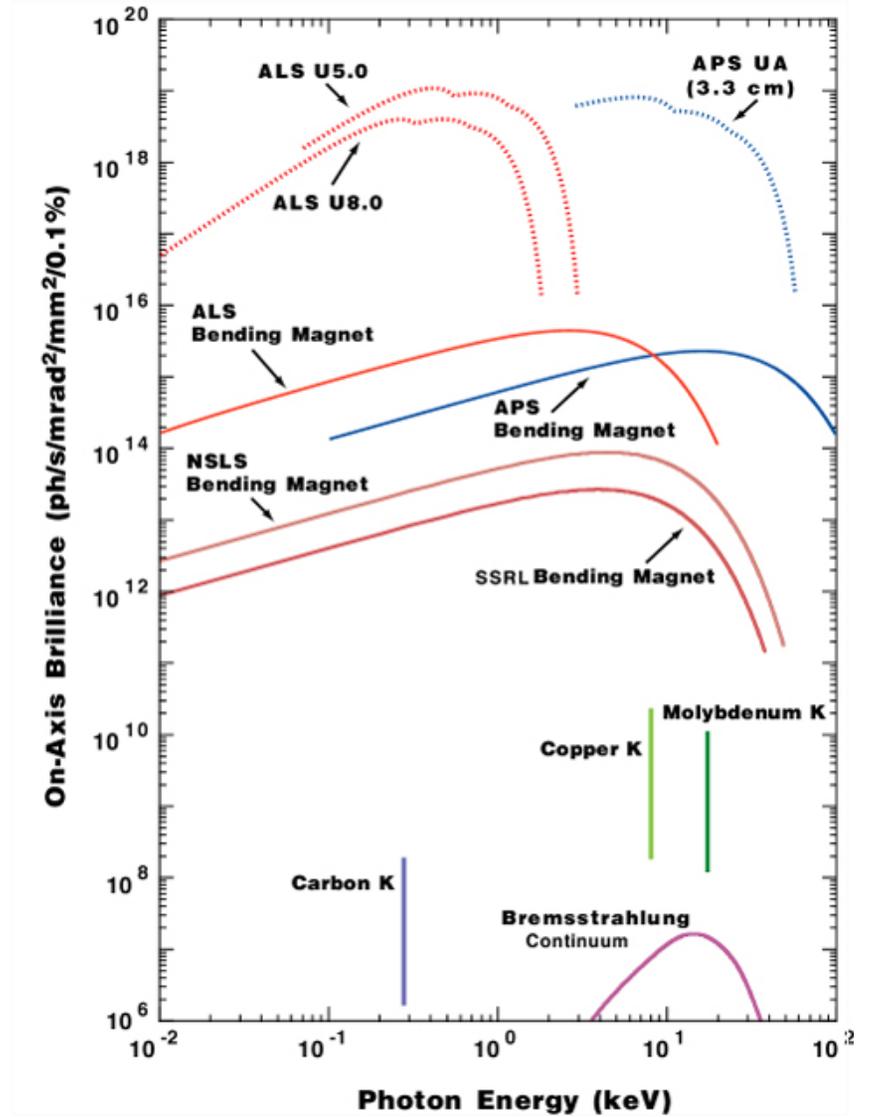

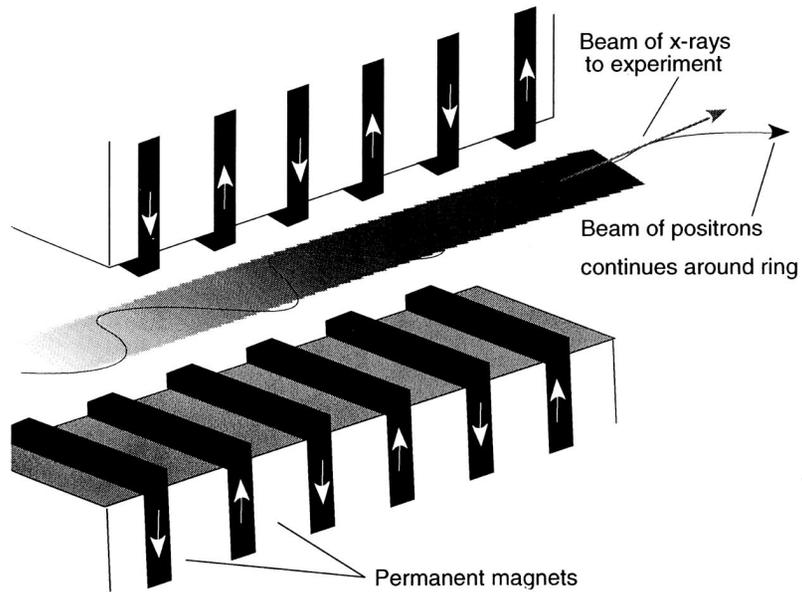

Where Do We Find High-Energy X-rays

Brilliance of Various Sources

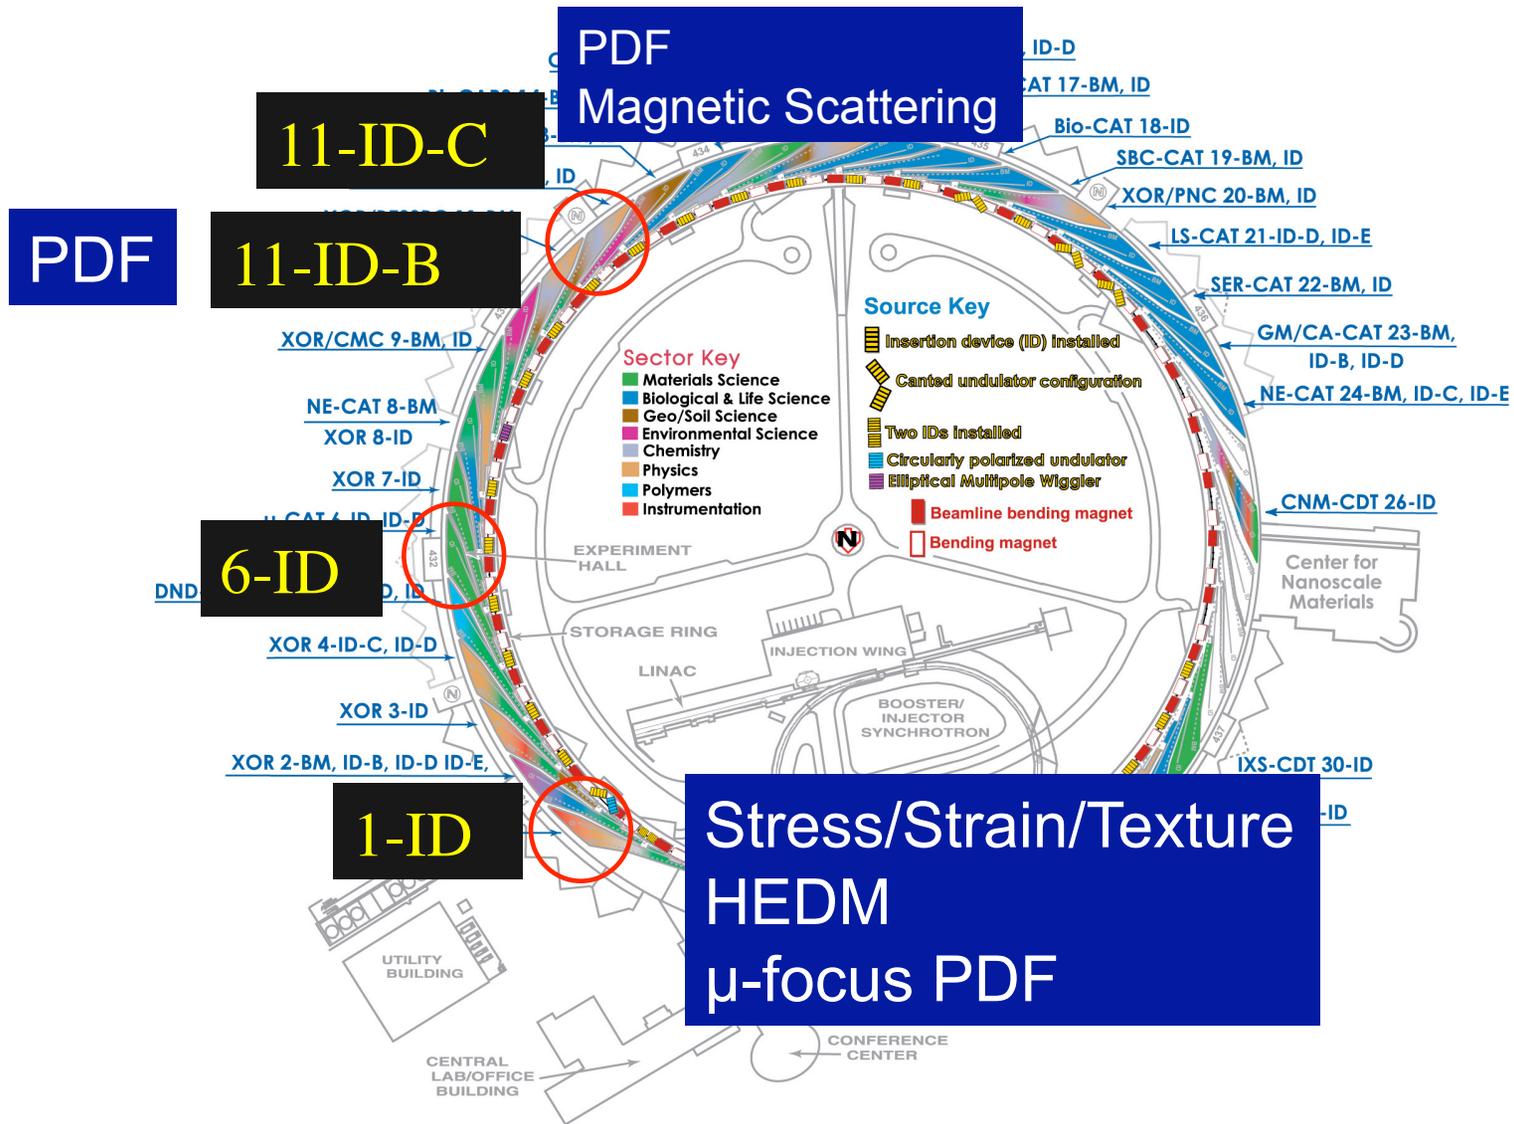

Brilliance of Various Sources

The Future Is Bright

APS High Energy Beamlines

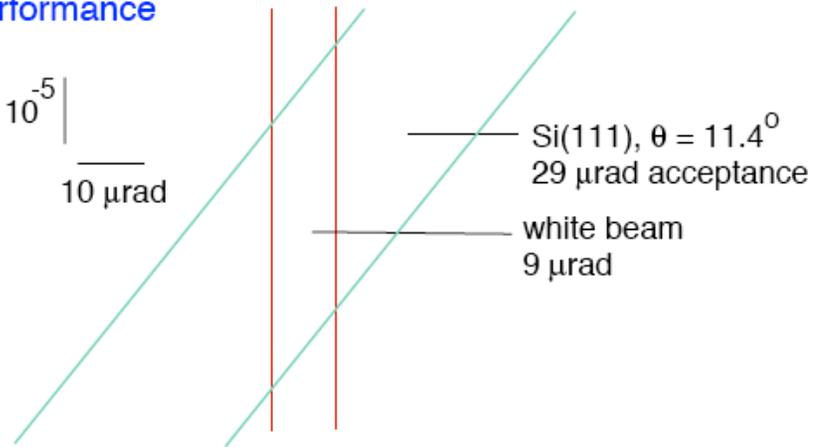

High Energy X-ray Optics

DuMond diagram of flat crystals

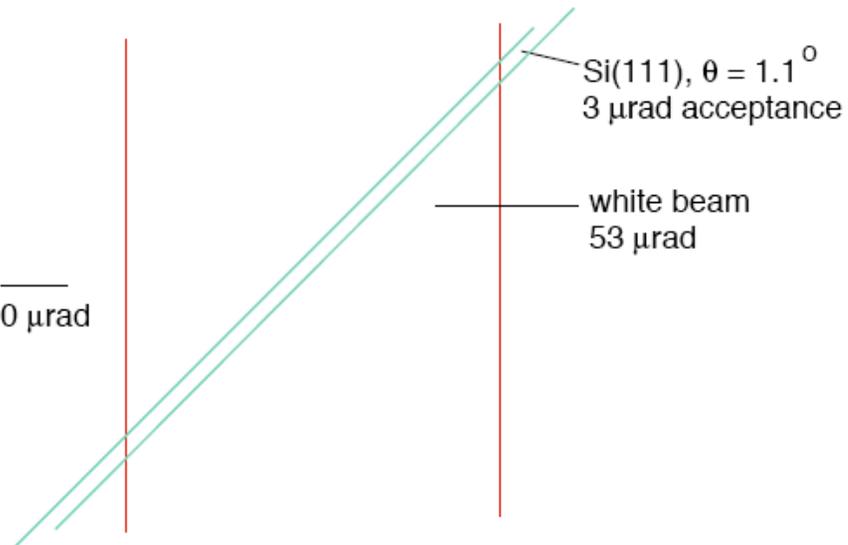

10 keV performance

$$\Delta E/E = 4 \times 10^{-5} \left| \begin{array}{l} \text{---} \\ 10 \mu\text{rad} \end{array} \right.$$

100 keV performance

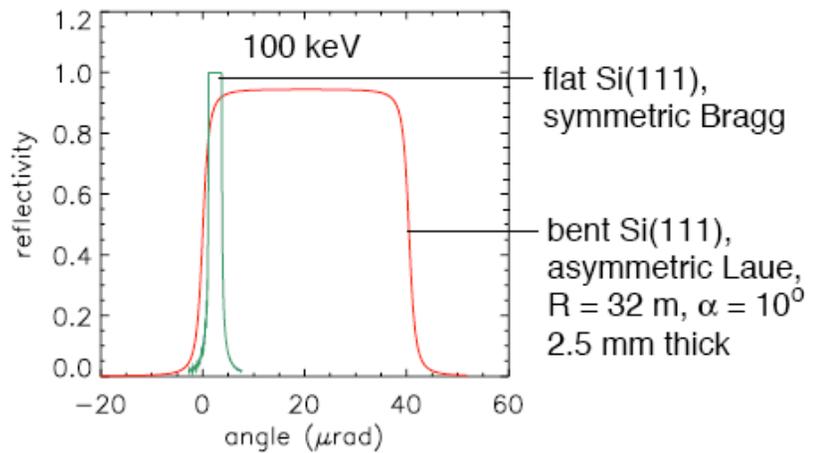

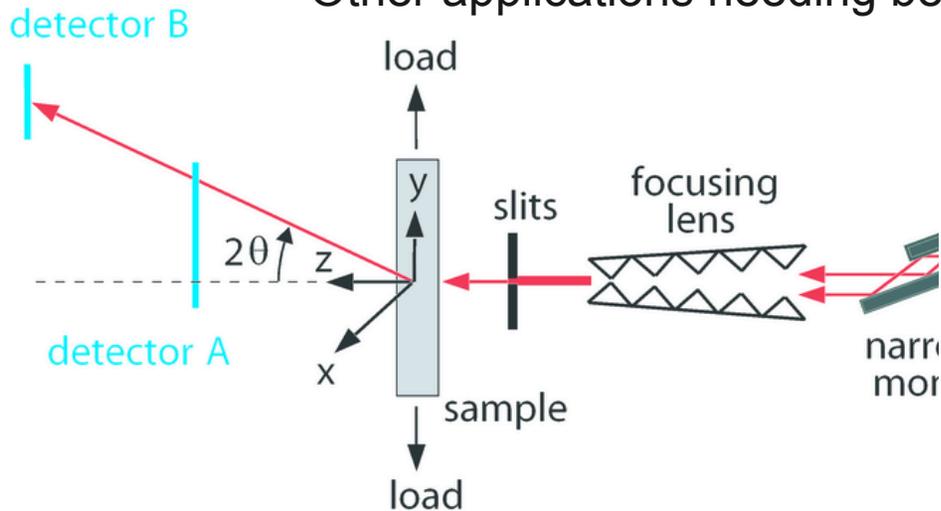

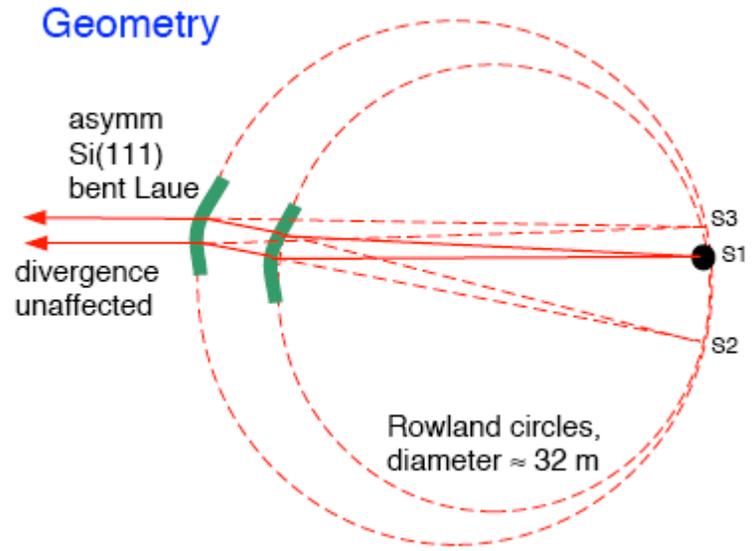

$$\Delta E/E = 5 \times 10^{-4} \left| \begin{array}{l} \text{---} \\ 10 \mu\text{rad} \end{array} \right.$$

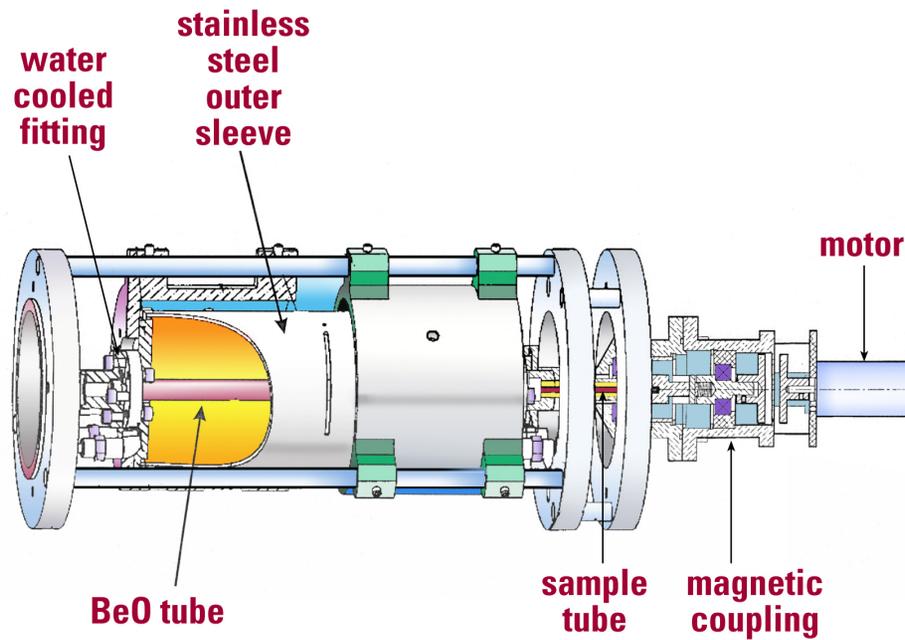

High Energy X-ray Optics at 1-ID

I-ID Optics

- Fully tunable 45 to 120 keV
- Brilliance preserving optics
- Compound optics
 - *Focusing*
 - ~2 μm possible
 - 20 μm typical
 - *High energy resolution*
 - Resonant scattering
 - Other applications needing better energy resolution

Special Environments

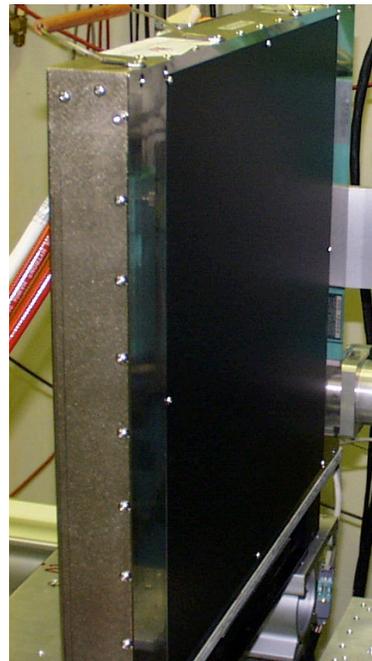

Kramer, Margulies, McCallum, Zhao, Goldman, Lee, & Haeffner

Detectors

Bruker 6500 CCD

GE Rad detector

Mar345 on-line image plate

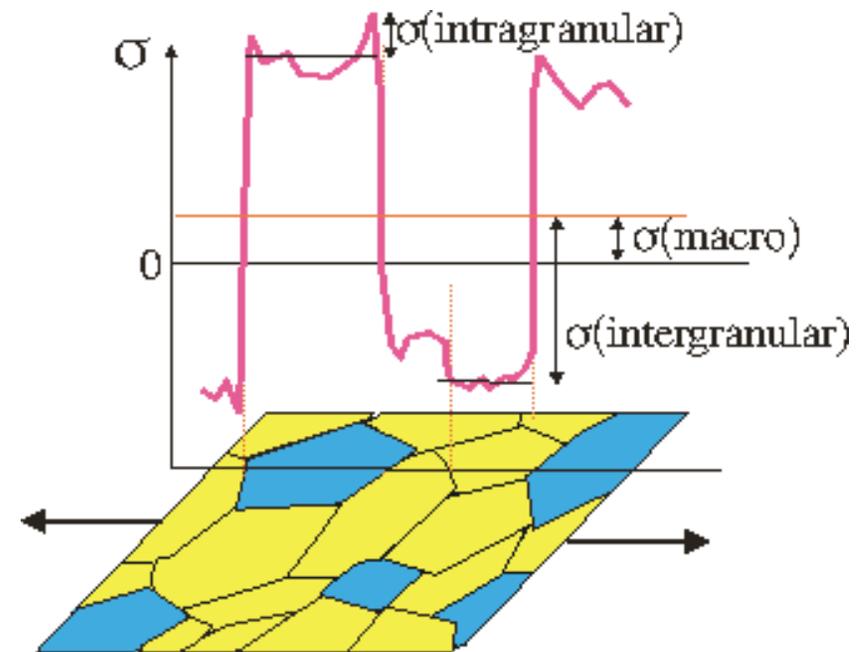

Example 1: Aggregate Stress/Strain/Texture

1. Powder limit: $N > \sim 1000$

- Average strain and orientation distribution (texture).
- Useful if gradients \gg grain size.
- Well-established techniques (esp. for surface: $\sin^2\psi$ method).

2. Finite N

- Grain boundary mapping, intragranular stress, local texture: “Grain-boundary engineering”
- Test local deformation models.
- Emerging techniques...

Absolute scale

—
0.01 - 1000 μm

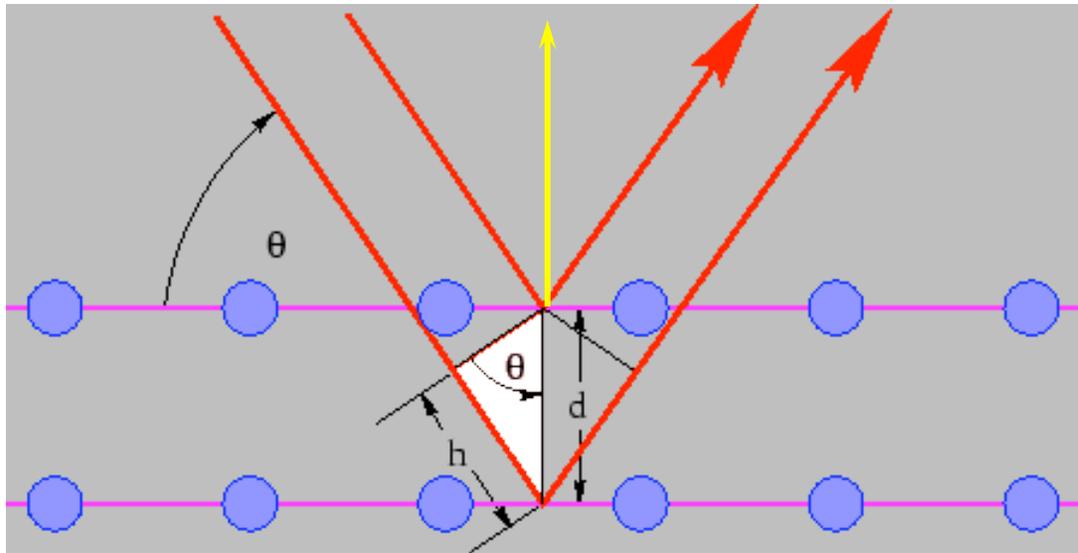

Nanoscience - Engineering

Local Strain and Texture Mapping with High-Energy X-rays

SR Property	Enables	Scale	Science
High-energies	High-penetration depths	many mm.	Bulk studies/complicated environments
Low emittance & high flux	Spatial resolution	μm	Local strains&texture
High flux (& area detectors)	Temporal resolution	(sub)sec.	Phase transitions, strain relaxation

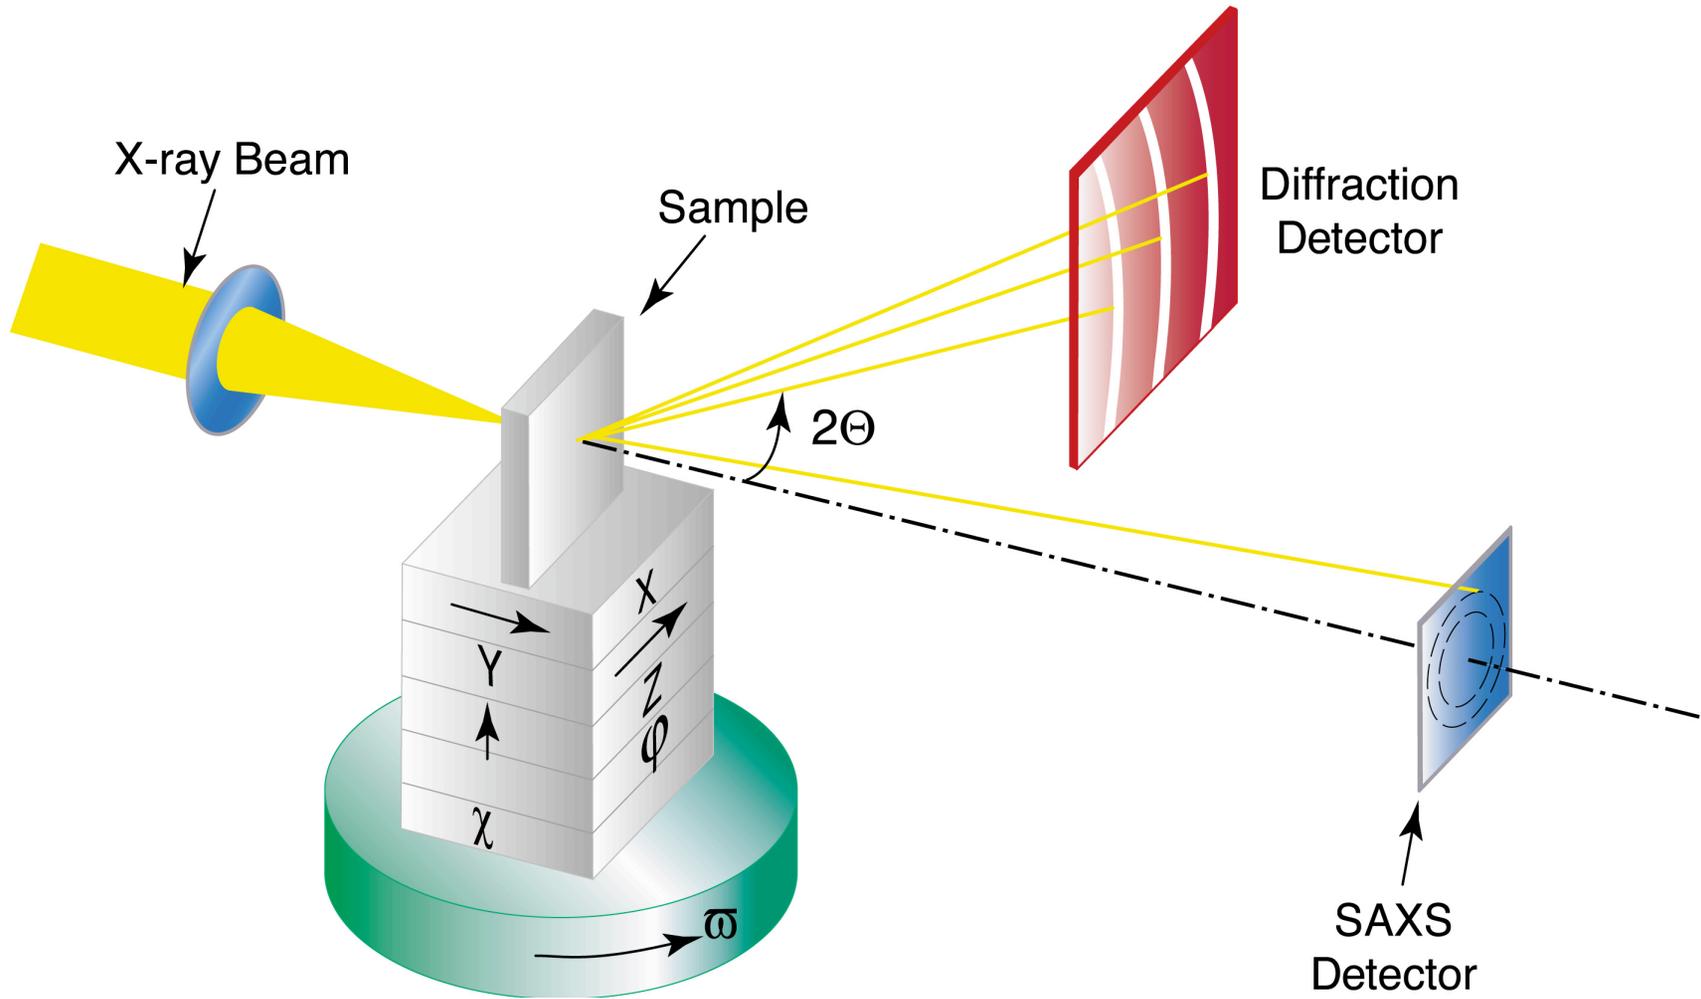

Aggregate Stress/Strain/Texture

Strain is measured with diffraction using Bragg's law

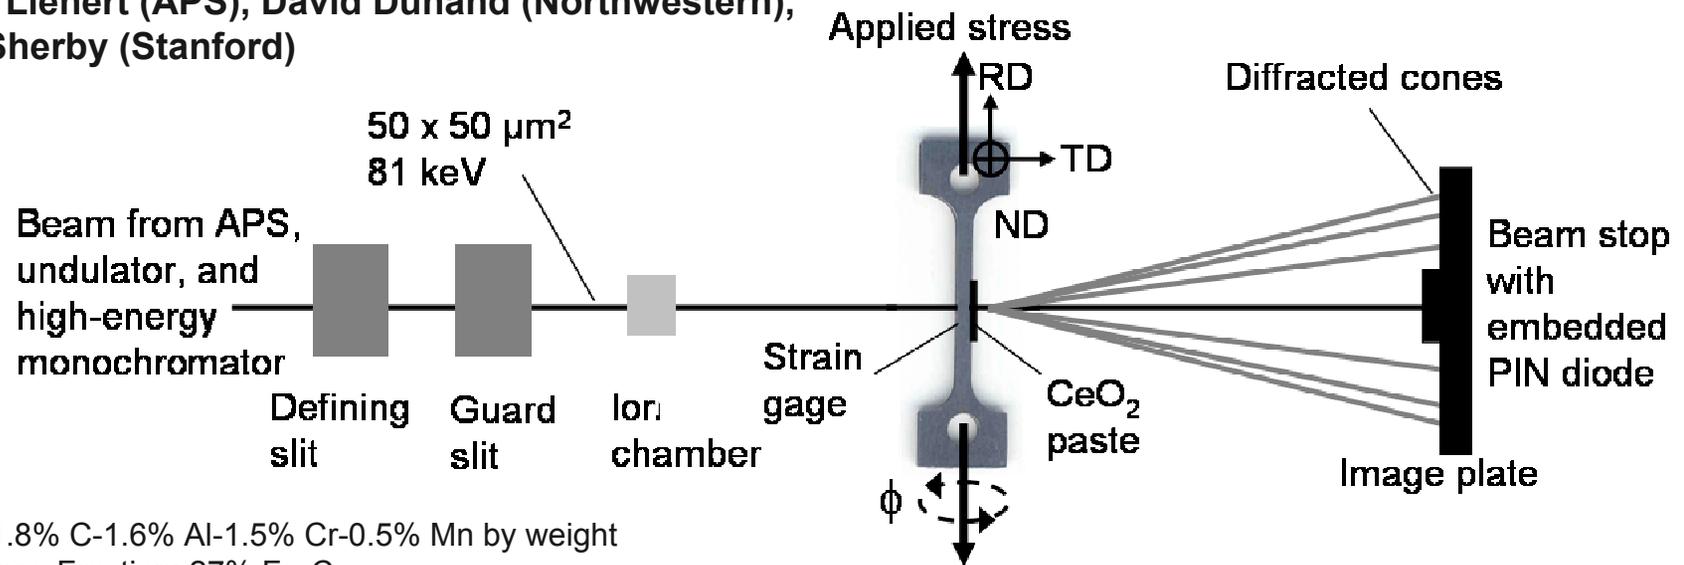

$$\lambda = 2d \sin \theta$$

$$\varepsilon = \frac{d - d_0}{d_0} = \frac{\sin \theta_0}{\sin \theta} - 1$$

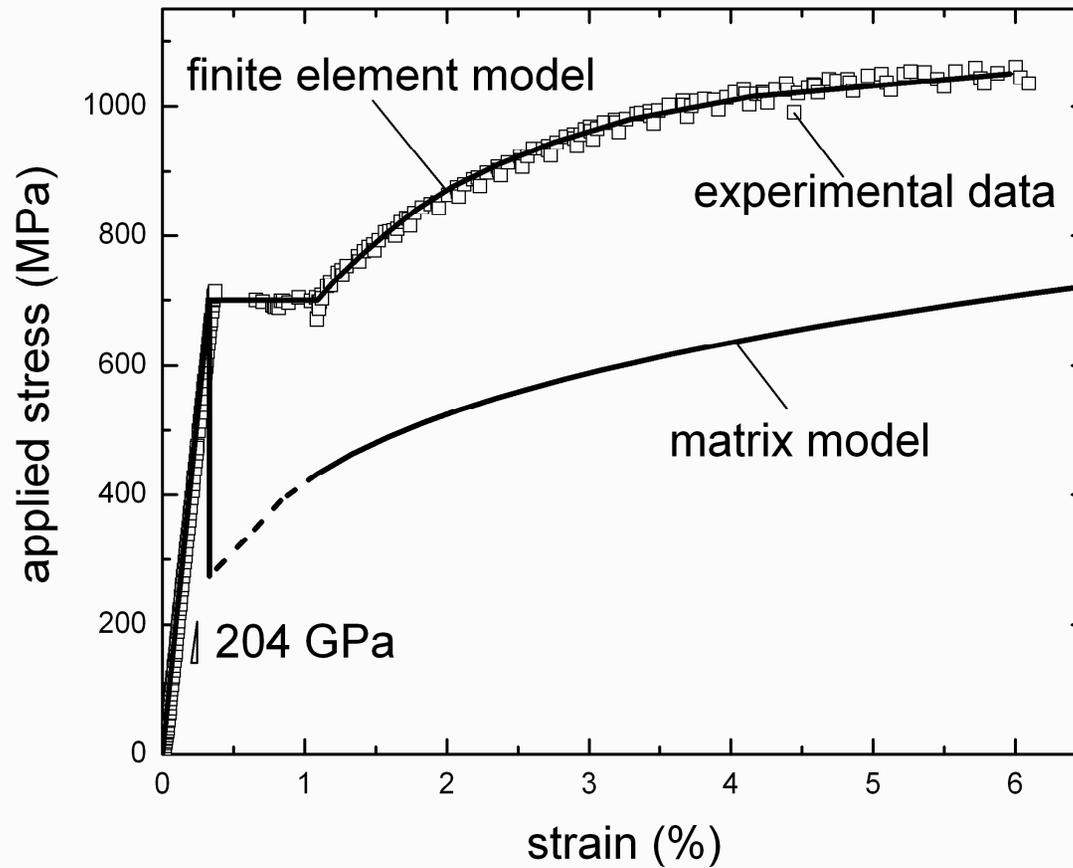

Load Partitioning in Ultrahigh Carbon Steel (UHCS)

Marcus Young (Northwestern/ANL), Jon Almer, Ulrich Lienert (APS), David Dunand (Northwestern), Oleg Sherby (Stanford)

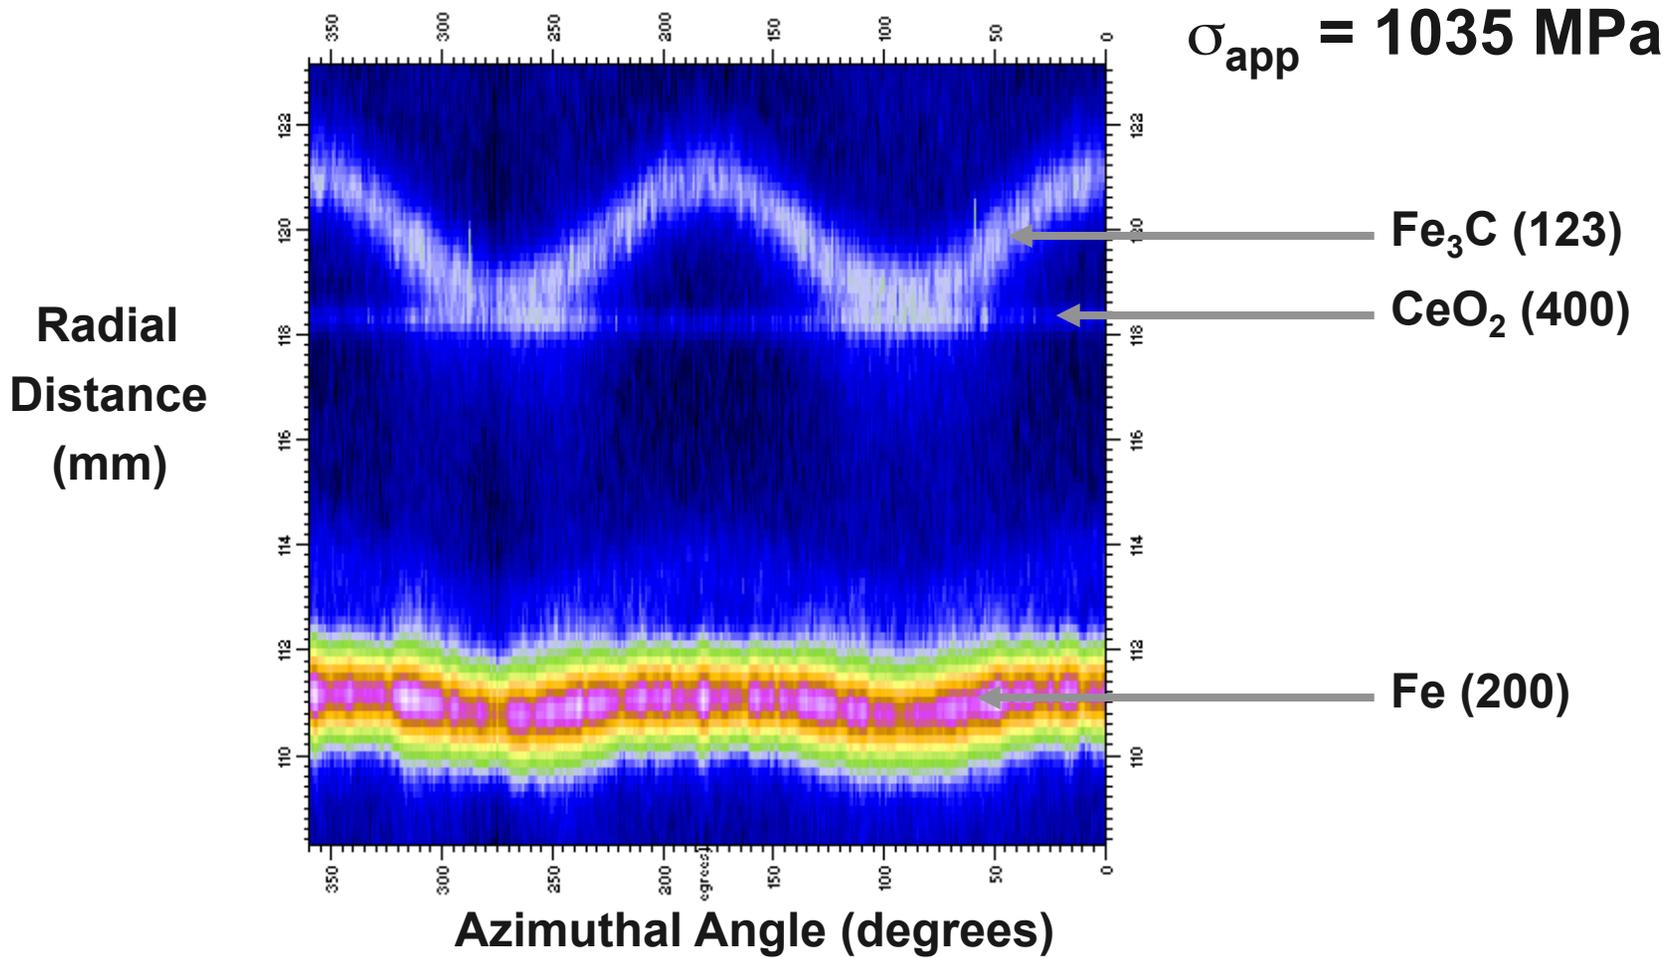

- Fe-1.8% C-1.6% Al-1.5% Cr-0.5% Mn by weight
- Volume Fraction: 27% Fe₃C
- Processing:
 - Soaked at 1093 °C for 8 hrs
 - Hot-rolled in several steps from 1093 °C to 900 °C
 - Hot-sheared into segments
 - Soaked at 1093 °C for 48 hrs & furnace-cooled
 - Reheated to 810 °C
 - Warm-rolled continuously to 750 °C
 - Additional Anneal:
 - Held at 200 °C for 1 hr
 - Heated to 950 °C for 20 min in vacuum furnace
 - Furnace cooled

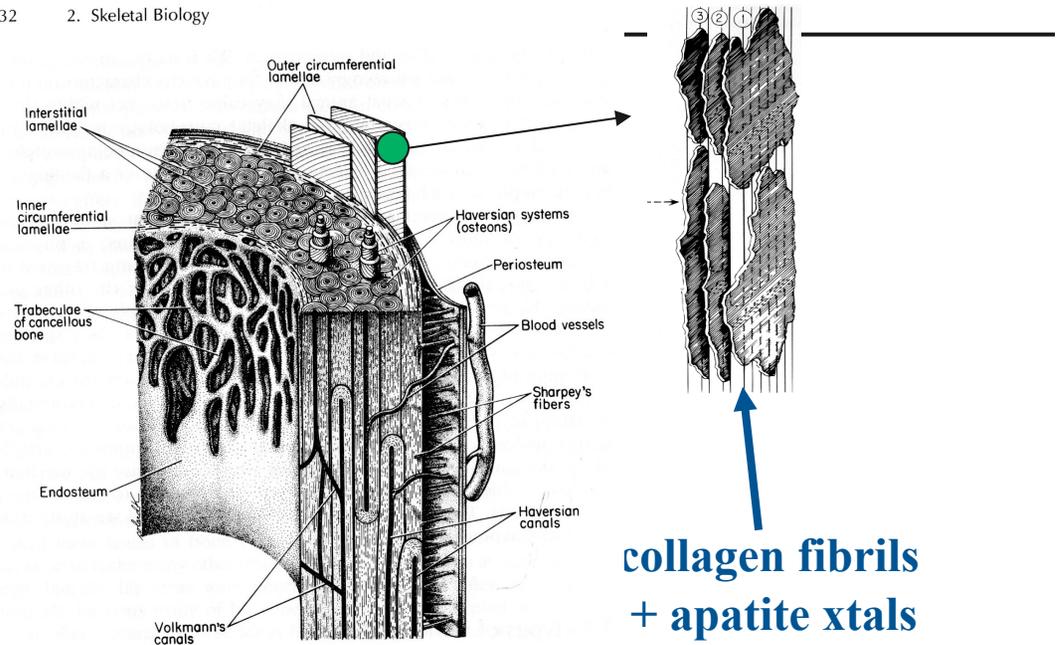

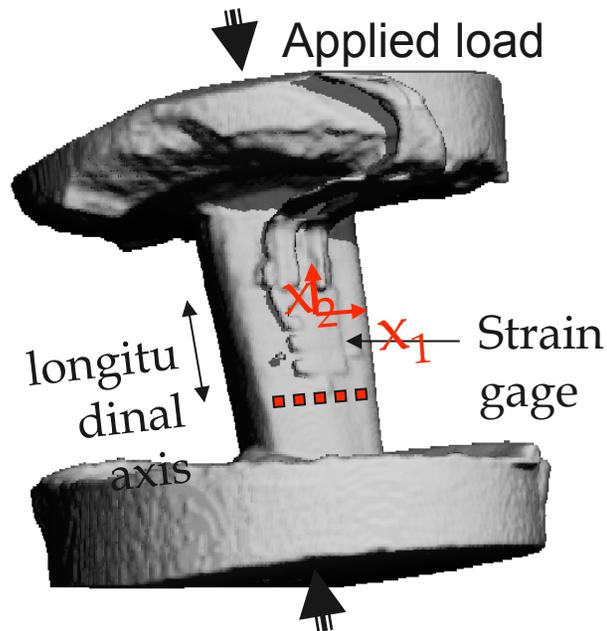

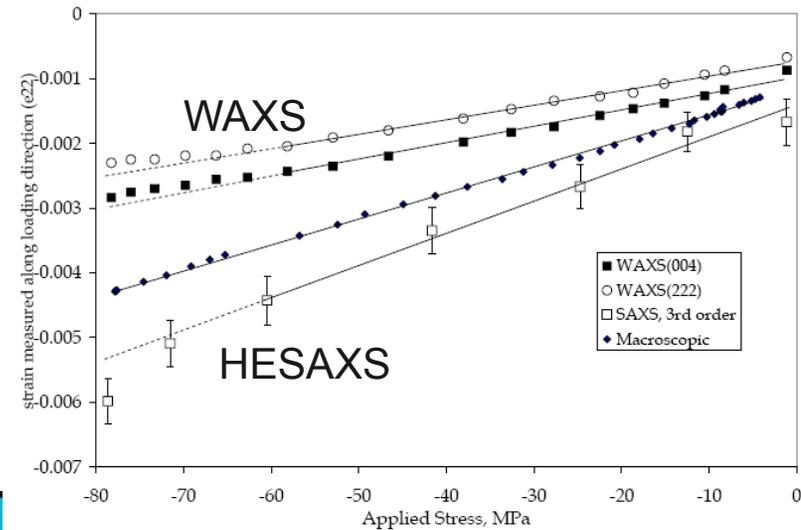

FIGURE 2.1. Sketch of some important features of a typical long bone. (After Benninghoff, 1949.)

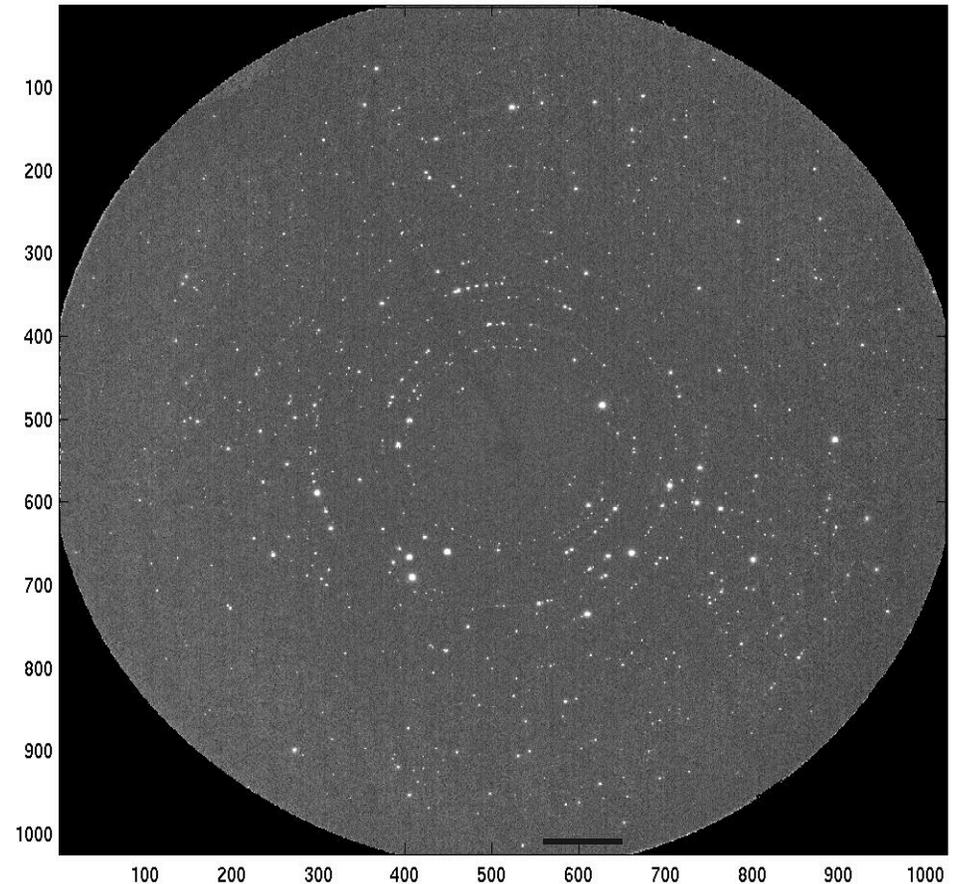

Example 2: High Energy Diffraction Microscopy (HEDM)

1. *Powder limit: $N > \sim 1000$*

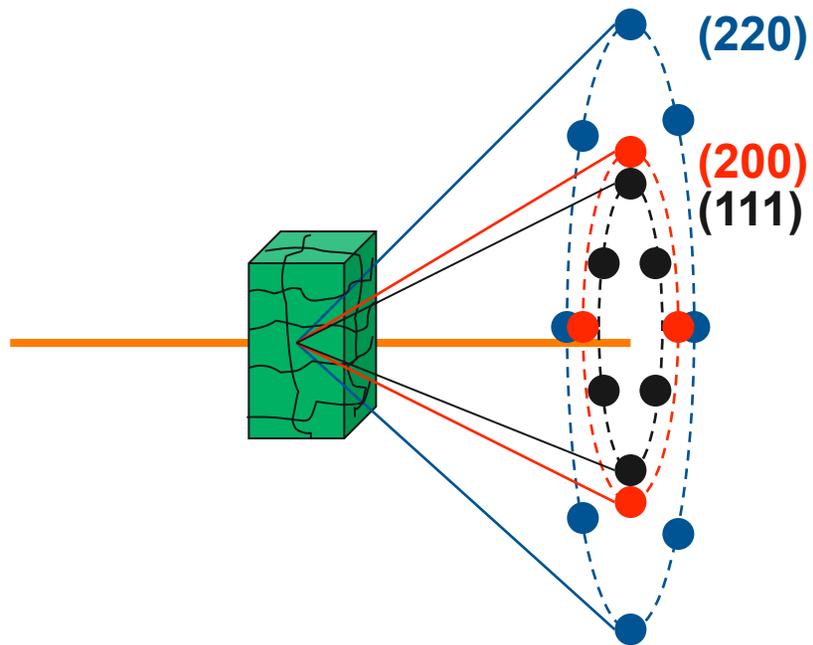

- Average strain and orientation distribution (texture).
- *Useful* if gradients \gg grain size.
- Well-established techniques (esp. for surface: $\sin^2\psi$ method).

2. *Finite N*

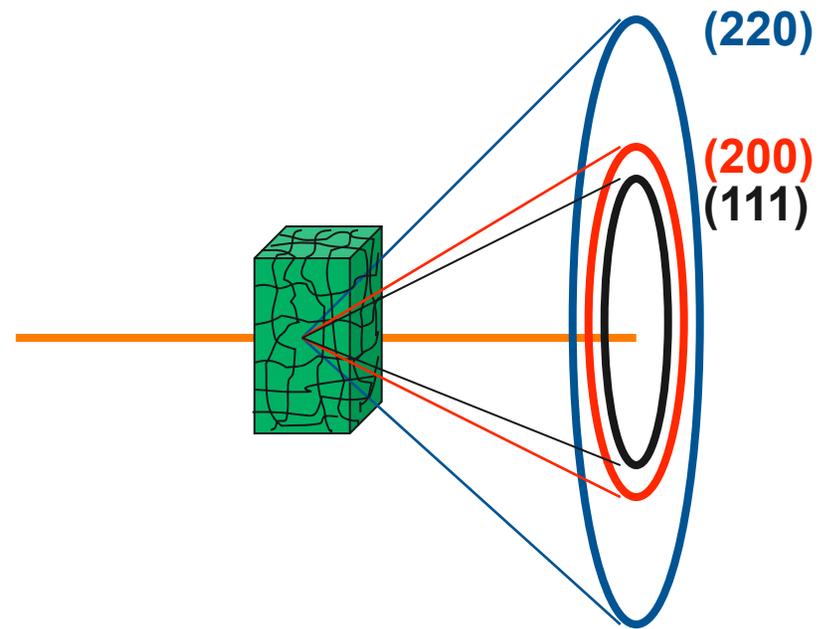

- Grain boundary mapping, intragranular stress, local texture: “Grain-boundary engineering”
- Test local deformation models.
- Emerging techniques...

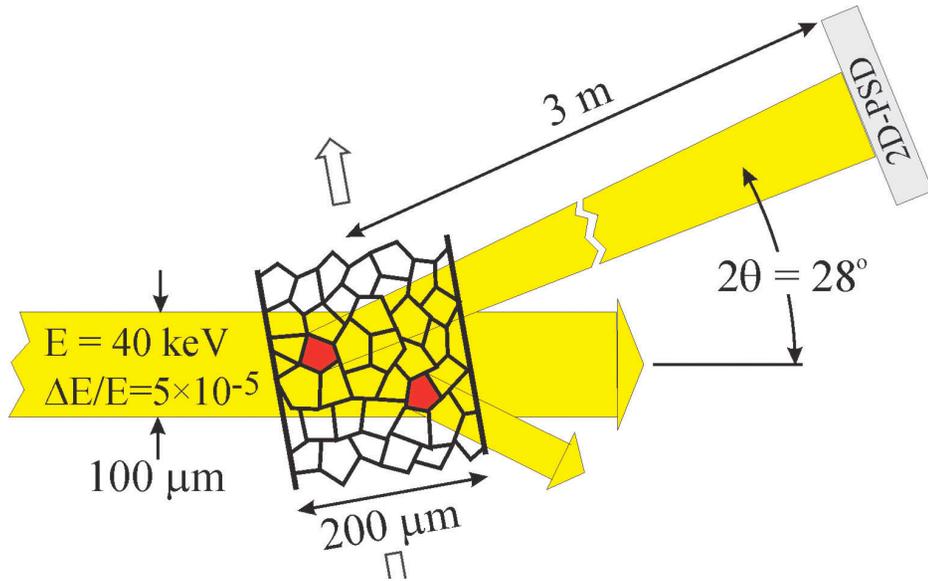

Coarse-grained material

Fine-grained material

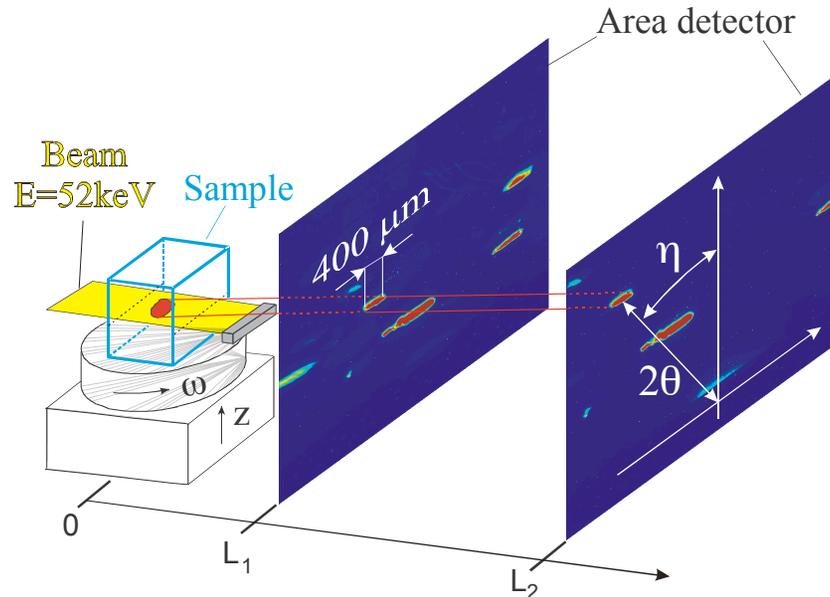

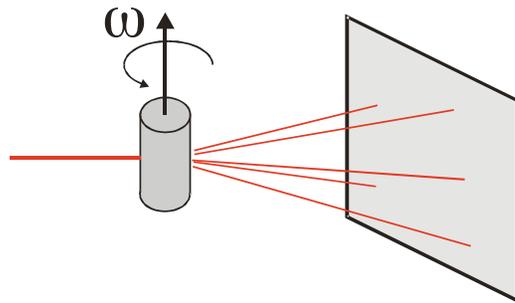

High Energy Diffraction Microscopy (HEDM)

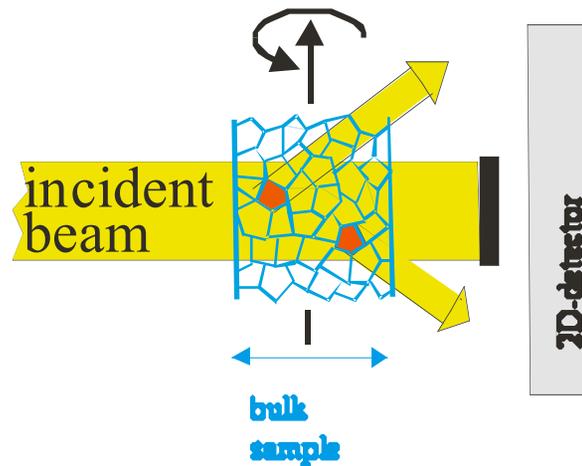

Several Modes

- Far field, medium q resolution
 - Grain rotation during deformation
- Far field, high q resolution
 - Dislocations cells & subgrain structure in Cu
- Tracking
 - Grain topography
 - Anomalous grain growth in Al

Ulrich Lienert
 Risø
 Suter Group, Carnegie Mellon

High Energy Single Grain Diffraction

- Orientation contrast
- Small scattering angles
- Intensity \propto volume
- 'parallel' data acquisition
- Multigrain indexing software
- Spot overlap
 - Linear in number of domains
 - Quadratic in orientation spread

Near field

- Position dominates strain
- Diffracted beams project grain outline

Far field

- strain dominates position
- 'sensitivity': < 0.1 mm (signal-to-noise)
- Spatial information: 'box scan'

High Resolution Reciprocal Space Mapping

Aim:

Characterization of evolving dislocation structure during plastic deformation:

Cell formation?
Subdivision?
Stability?
Strain?

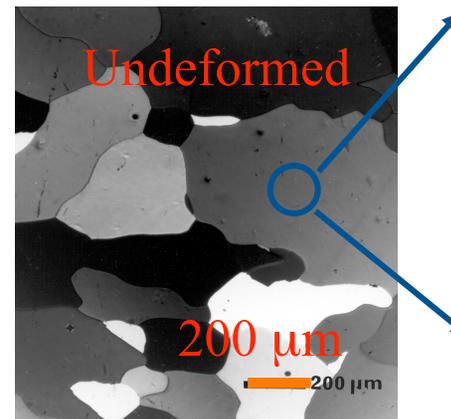

Samples:

FCC metals, tensile deformation up to 4.5%

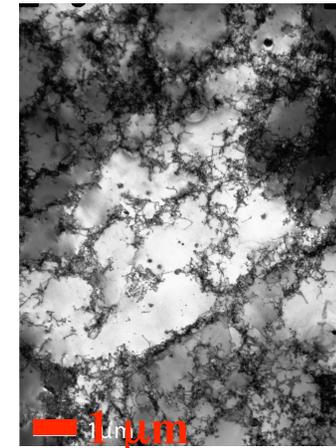

Experiment:

In-situ, bulk single grain probe

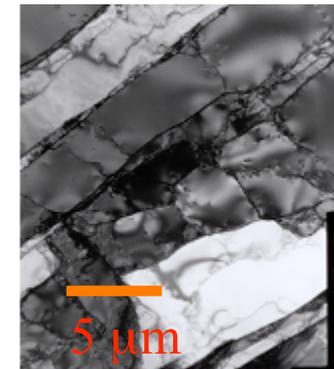

Far Field

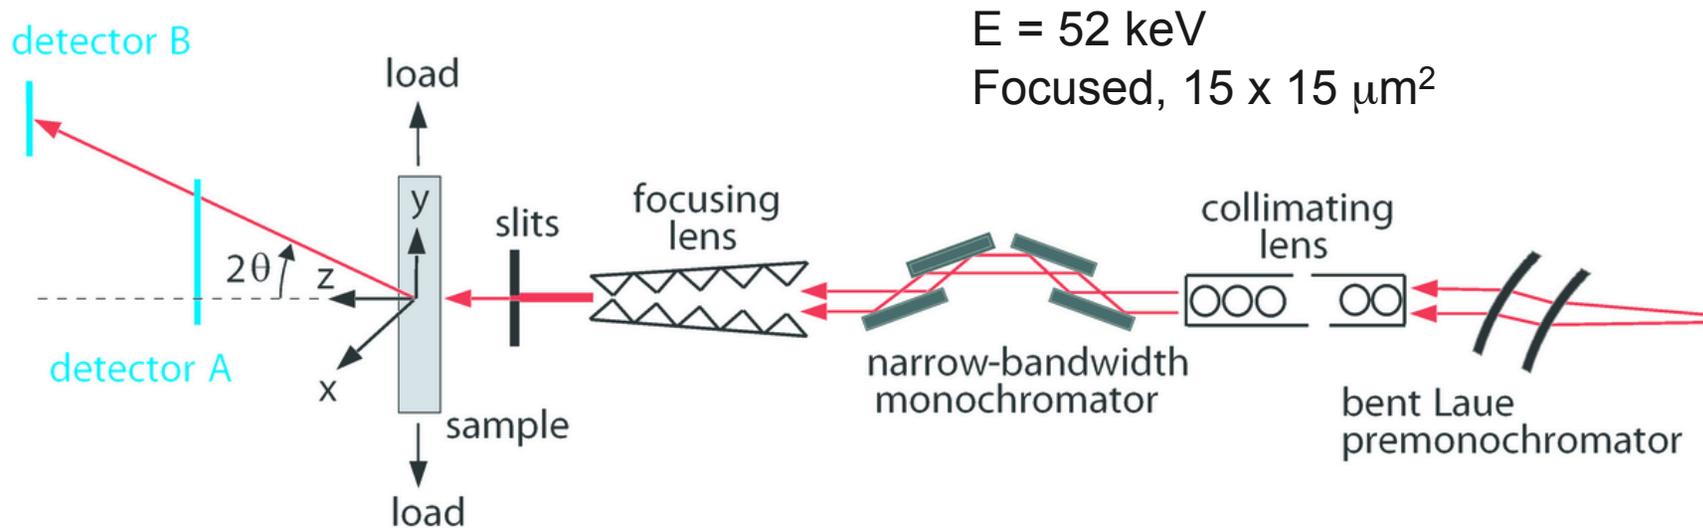

Small deformation

Large deformation

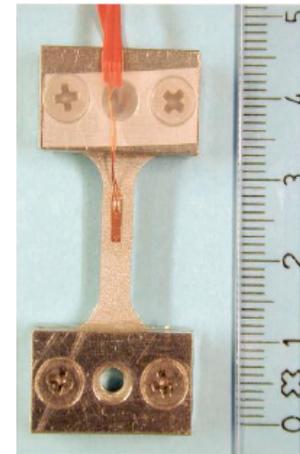

Setup at 1-ID

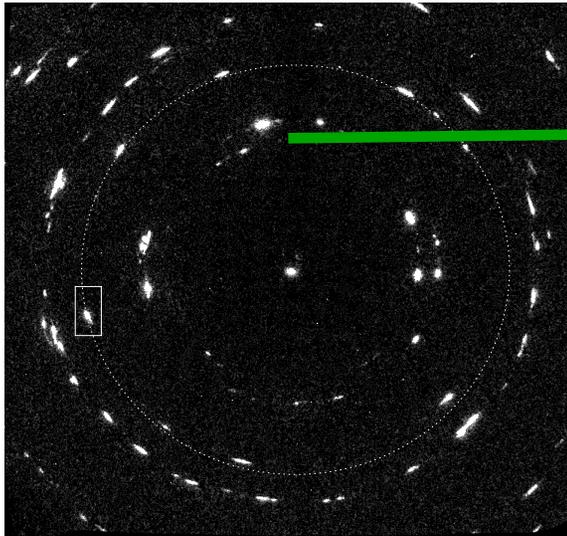

Samples

- Cu (99.99% OFHC)
- Cold rolled to 80% reduction, fully recrystallized
- Thickness $300 \mu\text{m}$, $30 \mu\text{m}$ grain size (EBSP)
- Displacement controlled tension rig
- $[400] \parallel$ load axis

Raw Diffraction Data

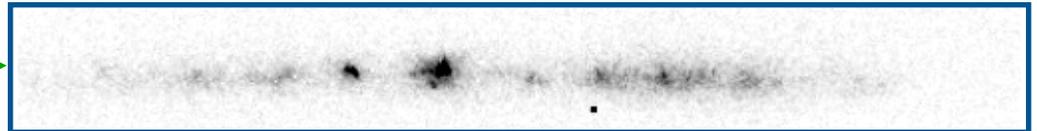

Detector A
40 cm from sample

Grain-scale

Detector B
4 m from sample

Zoom

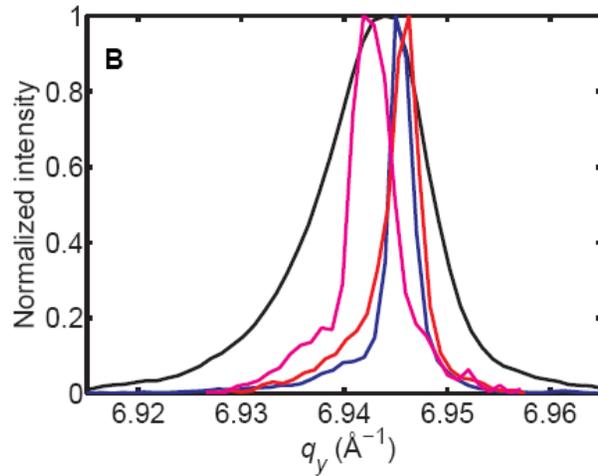

$\Delta\omega = 0.001$ deg

Subgrain-scale

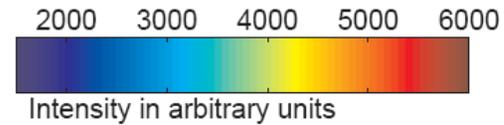

Cell & wall identification

Strain:

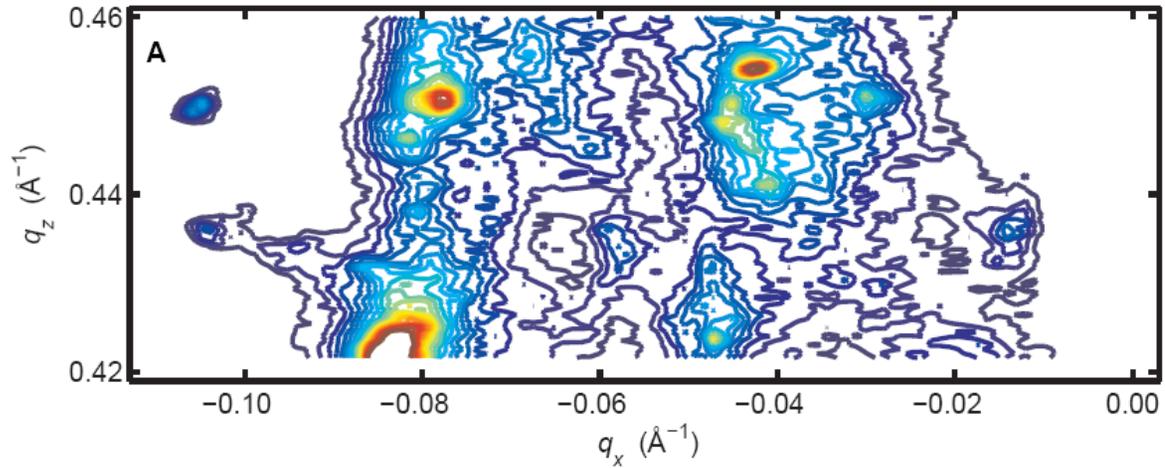

3D reciprocal space map
■ 400 Cu at 3.5% strain
■ Few minutes acquisition

Subgrains
■ Size 1-3 μm
■ Sharp peaks from unique sample positions

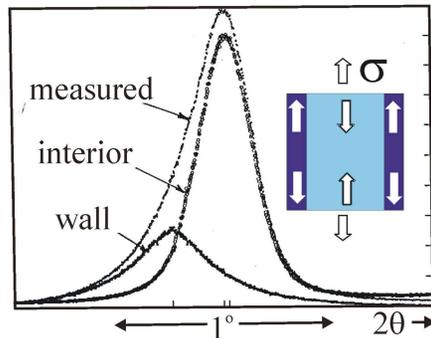

Mosaic spread:

B. Jakobsen et al., *Science* **312** (2006) 889-892

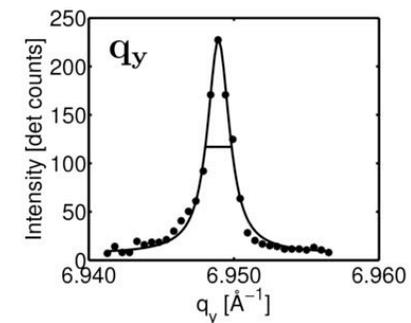

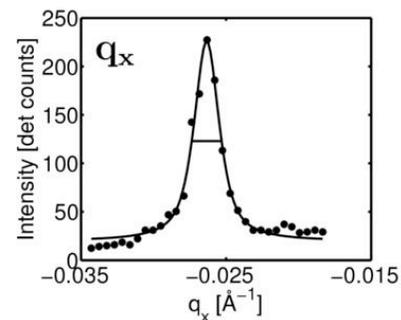

Axial Strain

Cu, ($\sigma \parallel 100$)

H. Mughrabi, T. Ungár et al., 1980's

- Macroscopic diffraction peak asymmetry
- Dislocation walls: forward stresses
- Dislocation-depleted regions: back stresses
- Each component broadened by respective dislocation density

■ Subgrains:

- < 12 dislocations in subgrain
- Homogeneous internal-strain
- Strains between subgrains
- Average back stress

■ Dislocation boundary regions

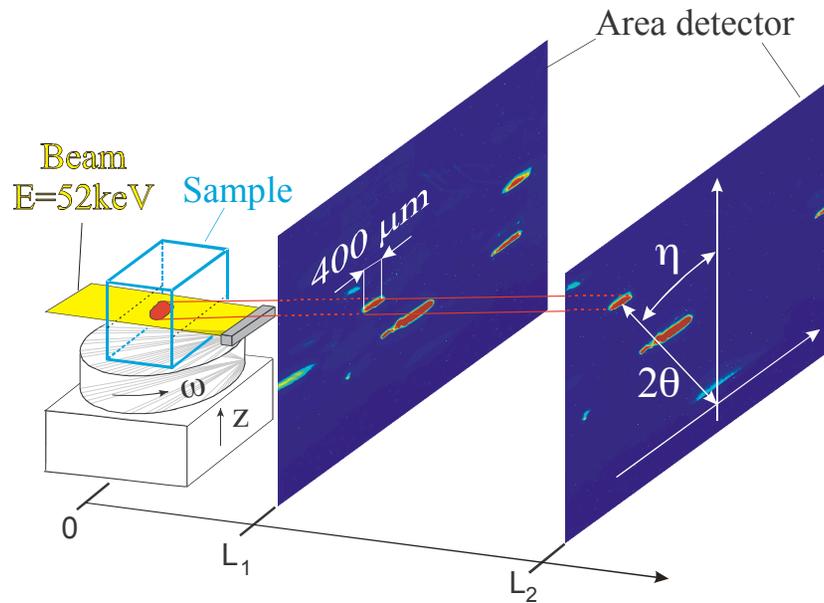

- Broad diffraction signal
- Average forward stress

B. Jakobsen et al. (2007) Acta Materialia 55: 3421

Diffraction Tracking

- Grain position, grain boundary topology
- Crystallographic phase & orientation

Near Field

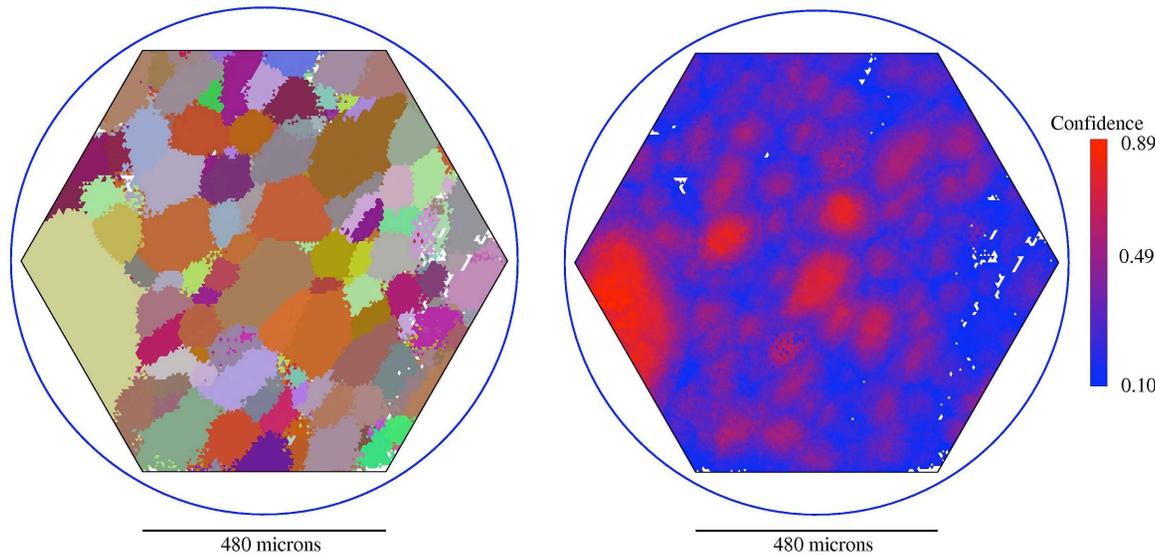

- Line focus
- Reflections by ω -rotation
- Projects grain cross section onto detector
- Backtracking \Rightarrow grain outline
- Grain orientation
- Some minutes per layer
- Limitation: mosaic spread

- Grain growth
- Phase transformation
- Initial state before processing

H.F. Poulsen *et al.*, J. Applied Cryst., 2001
R. Suter *et al.*

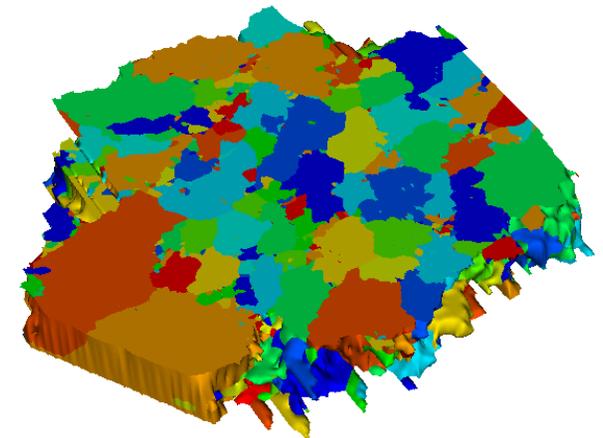

Polycrystalline grain maps

- Sample: aluminum 1050 polycrystal
- 500C anneal for 50 minutes
- EDM cut cylinder of about 1 mm diameter
- Data acquisition time per layer \approx 30 min

- \sim 24,500 triangular area elements
- Number of qualified Bragg peaks: 35 - 4
- Parallel algorithm implemented (B. Tieman, APS)

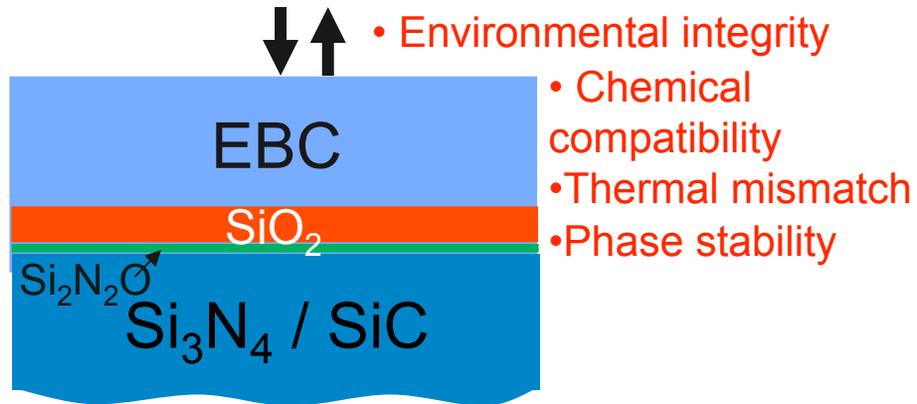

3D rendering
from 6 slices

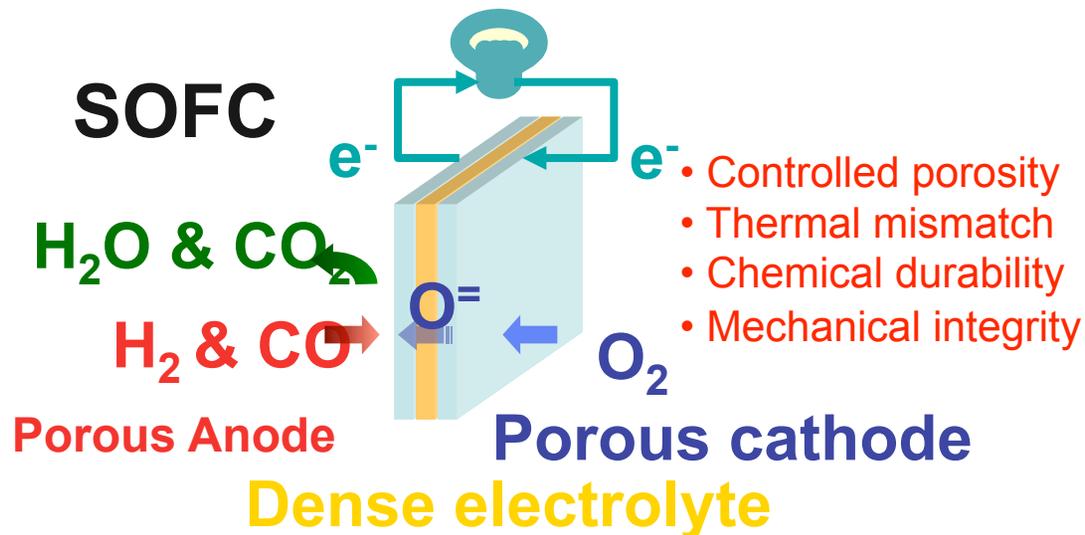

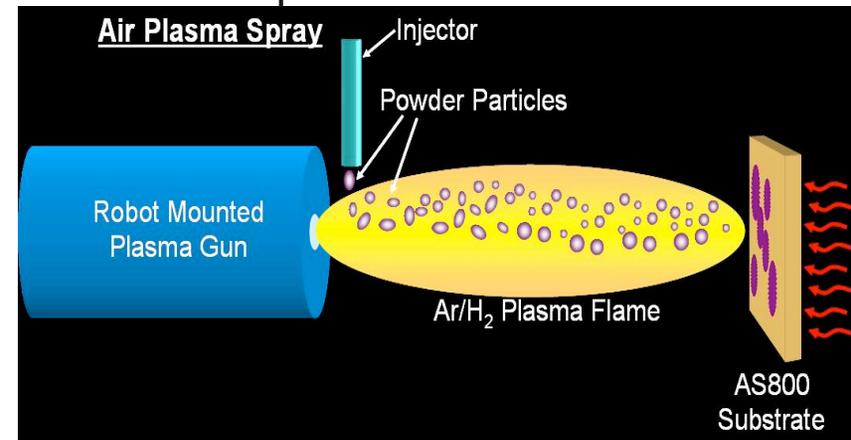

R.H. Moore, et al,
Comp. Mat. Sci.

Example 3: Layered System

Multiple requirements for functionality

Coating growth conditions often lead to non-equilibrium microstructures

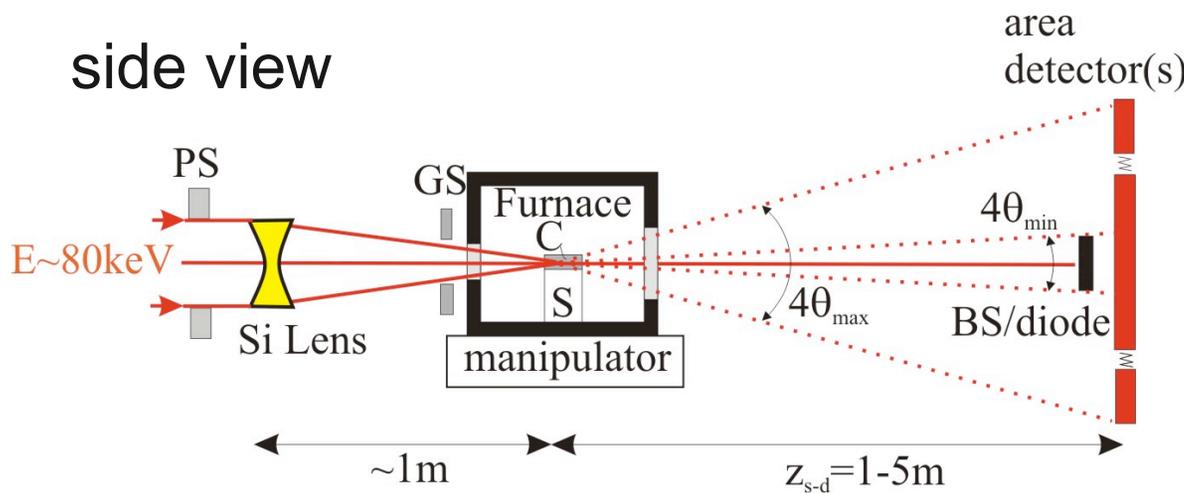

Investigate

- intra-layer microstructure
- inter-layer effects

Work of J. Almer

High-energy microfocusing to study layered systems

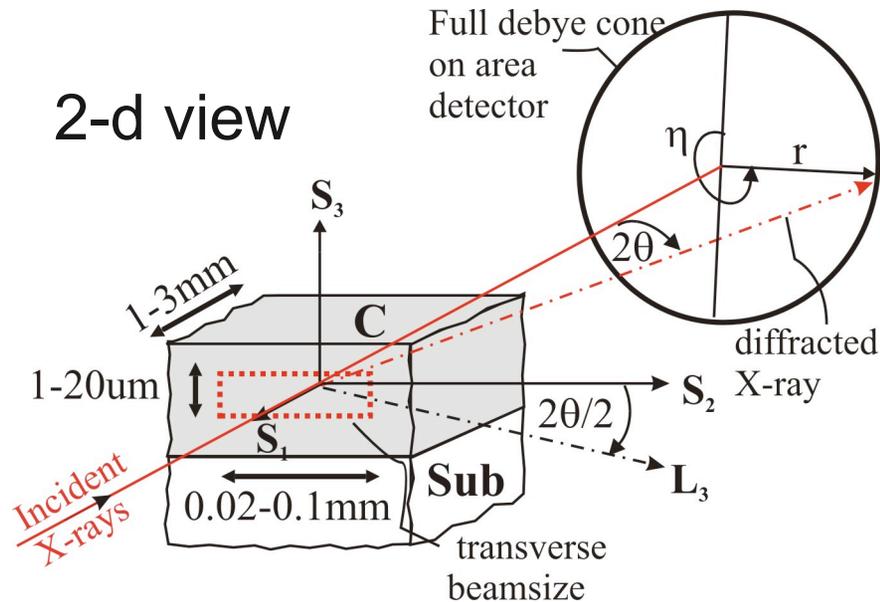

side view

Key features

- Focus vertical size to $\sim 1\mu\text{m}$ with sufficiently small divergence ($\sim 100\mu\text{rad}$)
- WAXS/SAXS/radiography on same sample volume
- High sample & chamber penetration power
- Small bragg angles – measure nearly along 2 principal sample directions
- Coatings typically isotropic in-plane: unique information in single exposure
- Direct depth resolution (cf. cumulative in reflection geometry)

2-d view

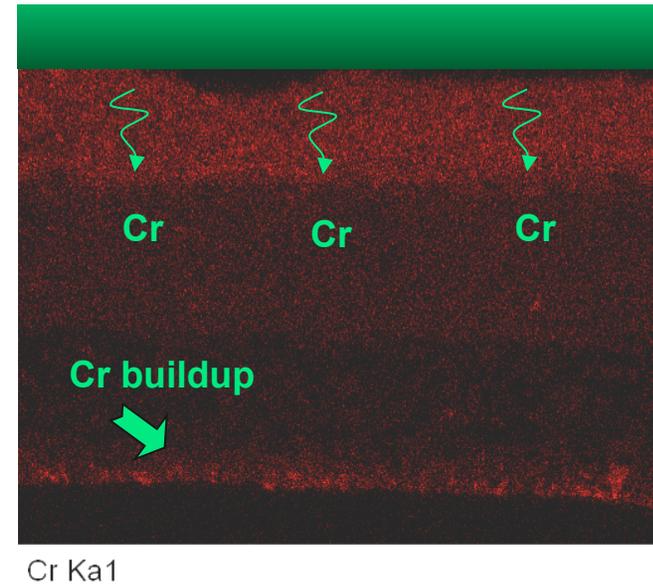

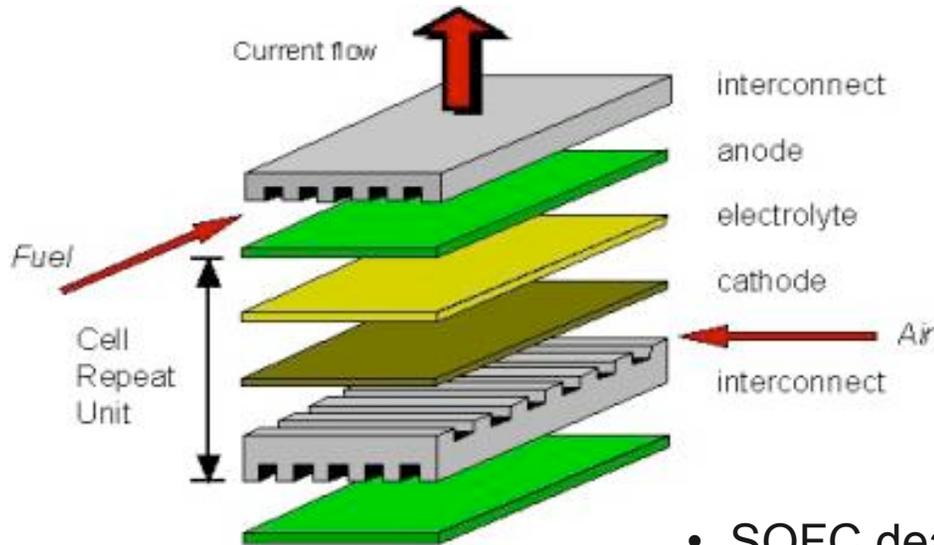

Solid-oxide fuel cells – Cr poisoning

Use of a metallic interconnect is a key to optimize SOFC efficiency & cost...

BUT

susceptible to Cr poisoning

- SOFC deactivation is often associated with Cr accumulation -> from metallic interconnect
- Knowledge of different Cr species & distribution is critical for understanding the deactivation mechanism
- Past experiments limited to imaging (SEM, EDX), inconclusive in separating phase & distribution
- Conventional XRD method lacks spatial resolution and sensitivity

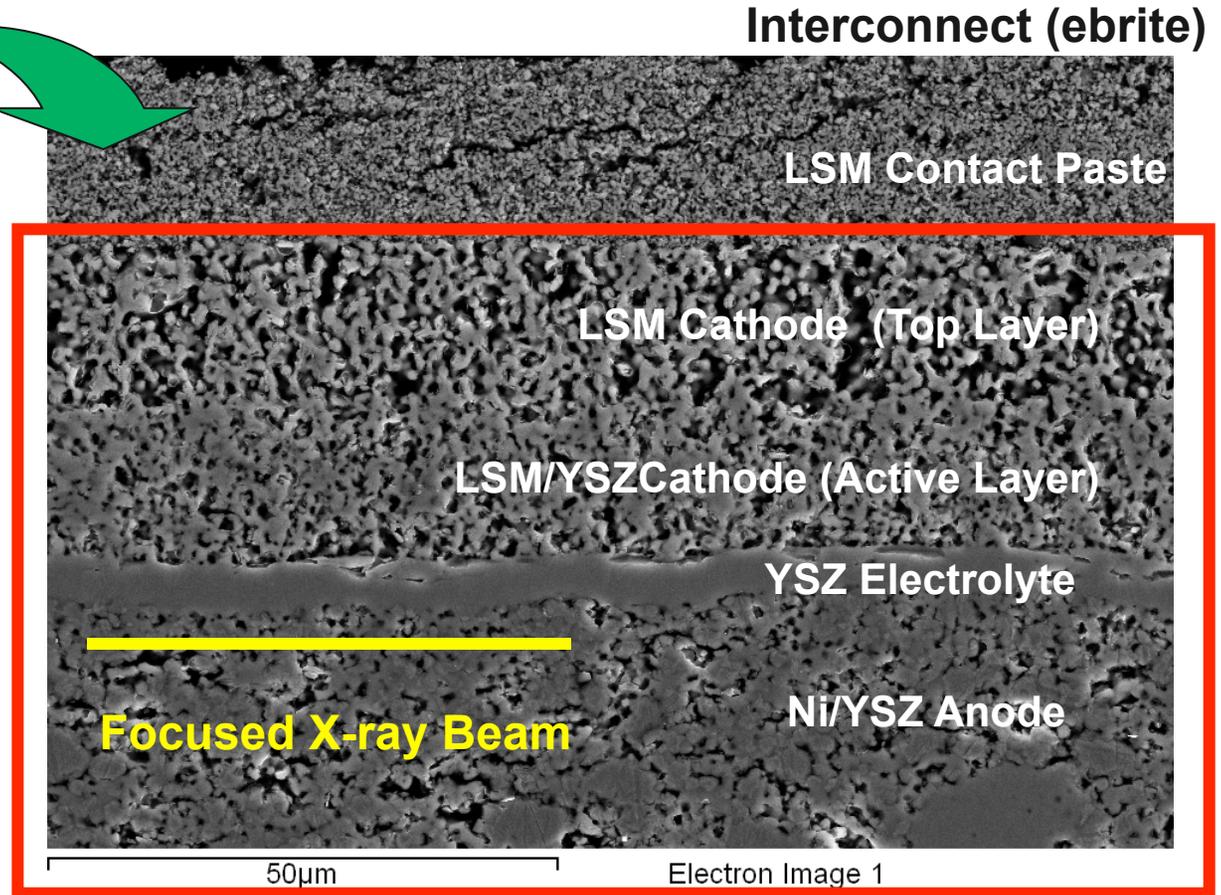

SOFC testing and microstructure

Cut 1mm cross-section from center

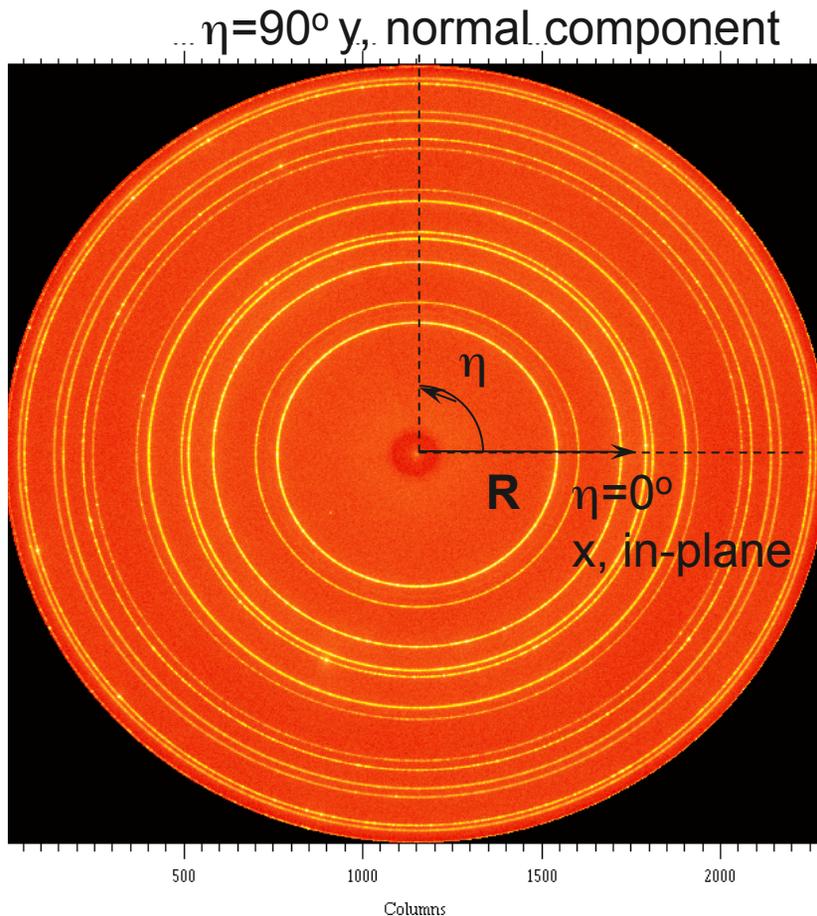

Button-cell testing

- Current Density 250 mA/cm²
- Air /fuel Flow 70/400 sccm
- T=800C
- Cell voltage to 0 (de-activation) after ~110hr test time

SEM Image of InDec SOFC Cross-section

SOFC diffraction data and analysis

Typical pattern (multiple phases)
Mar345, E=80.7 keV

Intensity

- Smooth & constant vs η (fine grained, no texture)
- Reliable Reitveld phase fractions (w_i)

Radius versus azimuth

- deviatoric strain
- $\Delta\varepsilon = - (r_{xx} - r_{yy})/r_{mean}$

Mean radius

- Reitveld \rightarrow lattice parameters
- stoichiometry

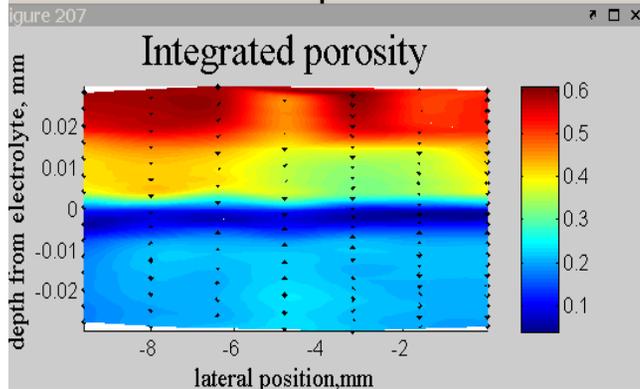

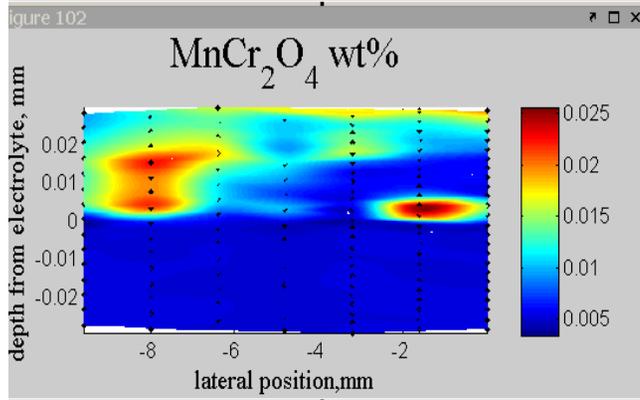

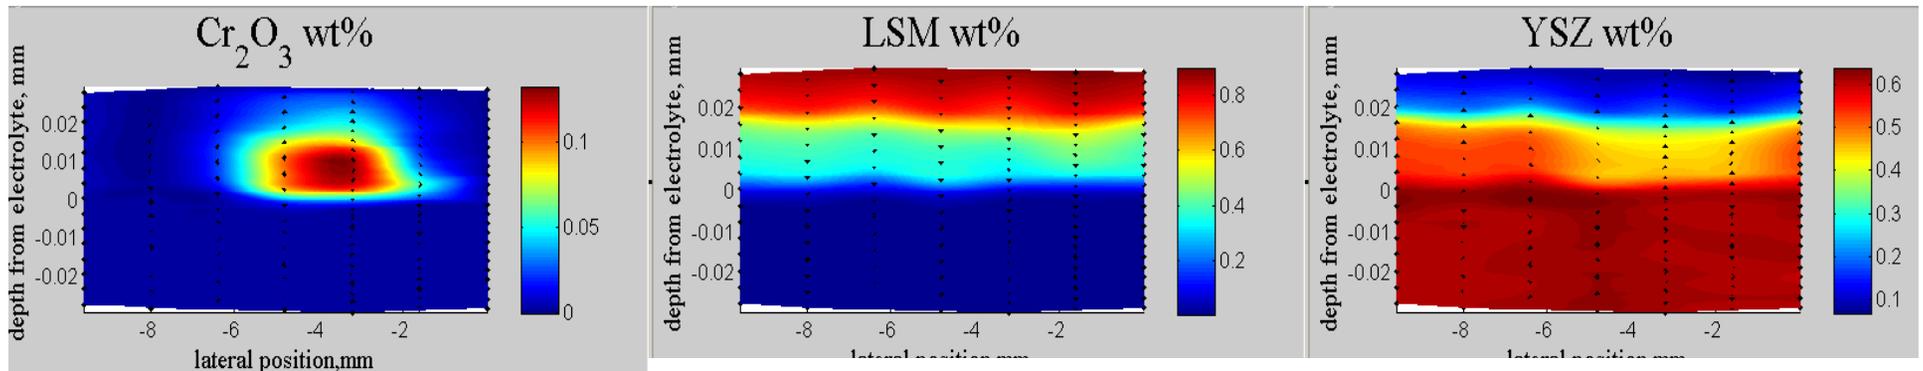

Sample transmission & phase fractions

- Integrated porosity

$$P_{int} = \frac{Z_{sam} - Z_{eff}}{Z_{sam}}$$

$$Z_{eff} = \frac{-\ln(T)}{\sum_{i=1}^N w_i \mu_i}$$

SOFC phase, porosity, strain & Ip maps

- Transition between 2 Cr phases in “active cathode” region
- Cr₂O₃ built up at cathode/electrolyte interface
 - Lateral dependence with current collector position
 - *suggests formation through electrochemical reduction*
 - Associated with decreased cathode porosity -> mass transfer of Cr
 - *Plays role in decreasing percolation -> increasing impedance*
- Cr/Mn spinel has weaker spatial association
 - *suggests chemical process (Cr gas transport & solid diffusion)*

Proposed mechanism of Cr poisoning

Cr Accumulation Mechanism

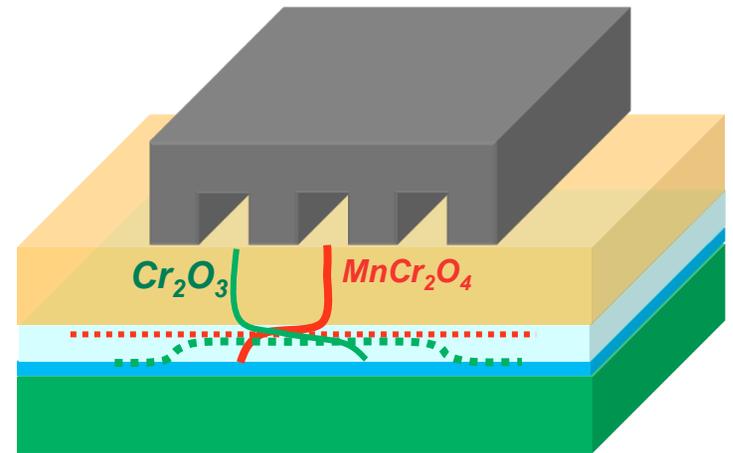

- Generation at metallic interconnect

- Deposition through Electrochemical Process¹

- Deposition through Chemical Process²

■ Solid-oxide fuel cells

- Depth-resolved porosity and phase analysis (SAXS/WAXS)
 - A. Allen, T. Dobbins, F. Zhao, J. Ilavsky, J. Almer and F. DeCarlo, *Cer. Eng.* 25(3), p. 275-80 (2004).
- Investigation of Cr-poisoning mechanism (J. Almer, D. J. Liu)

Conclusions/Comments

- The use of high energy x-rays present many new experimental possibilities for the study of materials.
- Stress/strain/texture can be studied in a wide variety of materials using both aggregate and single grain methods.
- Data from these experiments can help to verify/reject results from modeling.
 - We are always looking to establish better connections to theorists and modelers.
- More and more, these studies are being done under “real time” conditions to monitor materials evolution during processing, etc.
- Use of a combination of methods is a powerful methodology
 - Fuel cells as one example
- Improvements in undulators and x-ray optics will provide substantial gains x-ray flux density in the near future, providing exciting new capabilities.
