Magnetic Structure of MnO

(a)

Paramagnet
 $T > T_C$

(b)

Ferromagnet
 $T < T_C$

(c)

Antiferromagnet
 $T < T_N$

Magnetic Neutron Scattering directly probes the electrons in solids

Killer Application: Most powerful probe of magnetism in solids!

Magnetism = Net Angular Momentum

TABLE 1 Nuclear Magnetic Resonance Data

For every element the most abundant magnetic isotope is shown.
After Varian Associates NMR Table, 4th ed., 1964.

$$\vec{k} = \langle 0 \ 0 \ 1/2 \rangle$$

$$\vec{k} = \langle 1/2 \ 1/2 \ 0 \rangle$$

Magnetic Neutron Scattering

Neutrons carry no charge; carry $s=1/2$ magnetic moment

Only couple to electrons in solids via magnetic interactions

$$\mu_n = -\gamma \mu_N \sigma$$

$\gamma = 1.913$ nuclear magneton $= e \hbar / 2m_n$ Pauli spin operator

How do we understand what occurs when a beam of mono-energetic neutrons falls incident on a magnetic material?

Calculate a “cross section”:

What fraction of the neutrons scatter off the sample with a particular:

a) Change in momentum: $\kappa = \mathbf{k} - \mathbf{k}'$

b) Change in energy: $\hbar\omega = \hbar^2 k^2/2m - \hbar^2 k'^2/2m$

• Fermi's Golden Rule 1st Order Perturbation Theory

$$d^2\sigma/d\Omega dE' : \mathbf{k}, \sigma, \lambda \rightarrow \mathbf{k}', \sigma', \lambda'$$

$$= k'/k (m/2\pi \hbar^2)^2 |\langle \mathbf{k}' \sigma' \lambda' | V_M | \mathbf{k} \sigma \lambda \rangle|^2 \delta(E_\lambda - E_{\lambda'} + \hbar\omega)$$

kinematic

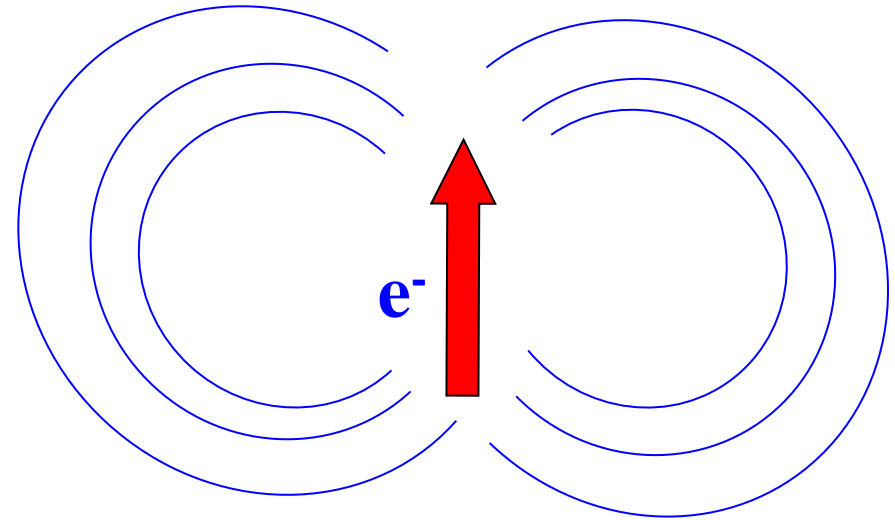

interaction matrix element

energy conservation

Understanding this means understanding:

V_M : The potential between the neutron and all the unpaired electrons in the material

$$V_M = -\mu_n B$$

**Magnetic Field
from spin $\frac{1}{2}$ of Electron: B_S**

**Magnetic Field
from Orbital Motion of Electrons: B_L**

The evaluation of $|\langle \mathbf{k}' \sigma' \lambda' | V_M | \mathbf{k} \sigma \lambda \rangle|^2$ is somewhat complicated, and I will simply jump to the result:

$$d^2\sigma/d\Omega dE' = (\gamma r_0)^2 k'/k \sum_{\alpha\beta} (\delta_{\alpha\beta} - \kappa_\alpha \kappa_\beta)$$

$$\times \sum \sum_{\text{All magnetic atoms at } d \text{ and } d'} F_{d'}^*(\boldsymbol{\kappa}) F_d(\boldsymbol{\kappa})$$

$$\times \sum_{\lambda\lambda'} p_\lambda \langle \lambda | \exp(-i\boldsymbol{\kappa} \mathbf{R}_{d'}) S_{d'}^\alpha | \lambda' \rangle \langle \lambda' | \exp(i\boldsymbol{\kappa} \mathbf{R}_d) S_d^\beta | \lambda \rangle$$

$$\times \delta(E_\lambda - E_{\lambda'} + \hbar\omega)$$

$$\text{With } \boldsymbol{\kappa} = \mathbf{k} - \mathbf{k}'$$

This expression can be useful in itself, and explicitly shows the salient features of magnetic neutron scattering

We often use the properties of $\delta(E_\lambda - E_{\lambda'} + \hbar\omega)$ to obtain $d^2\sigma/d\Omega dE'$ in terms of *spin correlation functions*:

$$d^2\sigma/d\Omega dE' = (\gamma r_0)^2/(2\pi\hbar) \quad k'/k \quad N\{1/2 g F_d(\mathbf{k})\}^2$$

$$\times \sum_{\alpha\beta} (\delta_{\alpha\beta} - \kappa_\alpha \kappa_\beta) \sum_l \exp(i\mathbf{k}\cdot\mathbf{l})$$

$$\times \int \langle \exp(-i\mathbf{k}\cdot\mathbf{u}_0) \exp(i\mathbf{k}\cdot\mathbf{u}_l(t)) \rangle$$

$$\times \langle S_0^\alpha(0) S_l^\beta(t) \rangle \exp(-i\omega t) dt$$

Dynamic Spin Pair Correlation Function

Fourier transform: $S(\mathbf{k}, \omega)$

Bottom Lines:

- **Comparable in strength to nuclear scattering**
- $\{1/2 g F(\boldsymbol{\kappa})\}^2$: **goes like the magnetic form factor squared**
- $\sum_{\alpha \beta} (\delta_{\alpha \beta} - \kappa_{\alpha} \kappa_{\beta})$: **sensitive only to those components of spin $\perp \boldsymbol{\kappa}$**
- **Dipole selection rules, goes like:** $\langle \lambda' | S^{\beta}_d | \lambda \rangle$;
where $S^{\beta} = S^x, S^y$ (S^+, S^-) or S^z

Diffraction type experiments:

Add up spin correlations with phase set by $\boldsymbol{\kappa} = \mathbf{k} - \mathbf{k}'$

$$\sum_1 \exp(i\boldsymbol{\kappa} \cdot \mathbf{l}) \langle S_0^{\alpha}(0) S_1^{\beta}(t) \rangle \quad \text{with } t=0$$

FIG. 13. Comparison of the experimental ^{152}Gd form factor at 96 K as measured by Moon *et al.*⁴⁷ with nonrelativistic Hartree-Fock and relativistic Dirac-Fock calculations by Freeman and Deaclaux.³⁶

Magnetic form factor, $F(\kappa)$, is the Fourier transform of the spatial distribution of magnetic electrons –

usually falls off monotonically with κ as $\pi/(1 \text{ \AA}) \sim 3 \text{ \AA}^{-1}$

Three types of scattering experiments are typically performed:

- Elastic scattering
- Energy-integrated scattering
- Inelastic scattering

Elastic Scattering

$$\hbar\omega = (\hbar\mathbf{k})^2/2m - (\hbar\mathbf{k}')^2/2m = 0$$

measures time-independent magnetic structure

$$d\sigma/d\Omega = (\gamma r_0)^2 \{ 1/2 g F(\boldsymbol{\kappa}) \}^2 \exp(-2W)$$

$$\times \underbrace{\sum_{\alpha\beta} (\delta_{\alpha\beta} - \kappa_{\alpha}\kappa_{\beta})}_{\mathbf{S} \perp \boldsymbol{\kappa} \text{ only}} \sum_l \exp(i\boldsymbol{\kappa}\cdot\mathbf{l}) \underbrace{\langle S_0^{\alpha} \rangle \langle S_l^{\beta} \rangle}_{\text{Add up spins with } \exp(i\boldsymbol{\kappa}\cdot\mathbf{l}) \text{ phase factor}}$$

$\mathbf{S} \perp \boldsymbol{\kappa}$ only

Add up spins with
 $\exp(i\boldsymbol{\kappa}\cdot\mathbf{l})$ phase factor

URu₂Si₂

$$\kappa = 0,0,1$$

$$a^* = b^* = 0:$$

everything within a basal plane (a-b) adds up in phase

$$c^* = 1:$$

2π phase shift from top to bottom of unit cell

π phase shift from corners to body-centre –good
but $\mu // \kappa$ kills off intensity!

Try $\kappa = 1,0,0:$

$\mu \perp \kappa$ good!

Mn^{2+} as an example: $1/2$ filled 3d shell $S=5/2$

$(2S+1) = 6$ states : $|S(S+1), m_z \rangle$

$m_z = +5/2 \hbar, +3/2 \hbar, +1/2 \hbar, -1/2 \hbar, -3/2 \hbar, -5/2 \hbar$

$H=0$; 6 degenerate states

$H \neq 0$; 6 non-degenerate states

$\langle 3/2 | S^- | 5/2 \rangle \neq 0 \rightarrow$ inelastic scattering

Magnetic sites are coupled by exchange interactions:

$$H = J \sum_{i,j} \mathbf{S}_i \cdot \mathbf{S}_j$$

Spin Wave Eigenstate:

“Defect” is distributed over all possible sites

Inelastic Magnetic Scattering : $|k| \neq |k^0|$

Figure 9 A spin wave on a line of spins. (a) The spins viewed in perspective. (b) Spins viewed from above, showing one wavelength. The wave is drawn through the ends of the spin vectors.

Study magnetic excitations (eg. spin waves)

Dynamic magnetic moments on time scale 10^{-9} to 10^{-12} sec

$$S(\kappa, \omega) = n(\omega) \chi''(\kappa, \omega)$$

Bose (temperature) factor

Imaginary part of the
dynamic susceptibility

Sum Rules:

One can understand very general features of the magnetic neutron Scattering experiment on the basis of “sum rules”.

$$1. \quad \chi_{\text{DC}} = \int (\chi''(\mathbf{\kappa}=\mathbf{0}, \omega)/\omega) d\omega \quad ;$$

where χ_{DC} is the χ measured with a SQUID

$$2. \quad \int d\omega \int_{\text{BZ}} d\mathbf{\kappa} S(\mathbf{\kappa}, \omega) = S(S+1)$$

$$T = 0.9 T_C$$

Symmetry broken

$$T = T_C$$

$\xi \sim$ very large

Origin of universality

$$T = 1.1 T_C$$

• Bragg scattering gives square of order parameter; symmetry breaking

• Diffuse scattering gives fluctuations in the order parameter

CsCoBr₃

Bragg scattering

$$Q=(2/3, 2/3, 1)$$

$$I=M^2=M_0^2(1-T/T_C)^{2\beta}$$

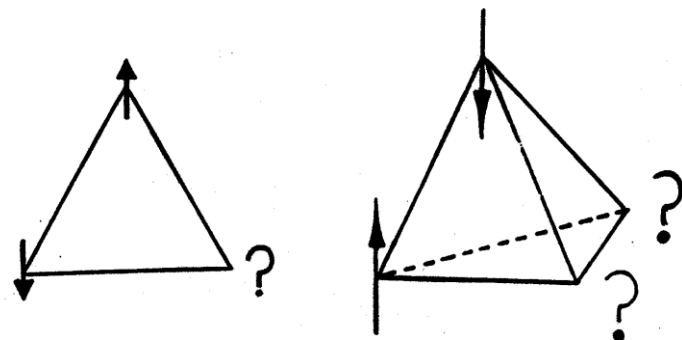

**Energy-integrated
critical scattering**

$$\frac{d\sigma(\vec{Q})}{d\Omega} = \frac{\chi(\vec{Q}_{ord})}{1 + \frac{q_a^2 + q_b^2}{\kappa_{ab}^2} + \frac{q_c^2}{\kappa_c^2}},$$

Geometrical Frustration:

The cubic pyrochlore structure;
A network of corner-sharing tetrahedra

neutron diffraction from
 $\text{Tb}_2\text{Ti}_2\text{O}_7$

**A^{3+} site within a distorted cube
of 8 O^{2-} ions – unique direction
pointing into or out of tetrahedra**

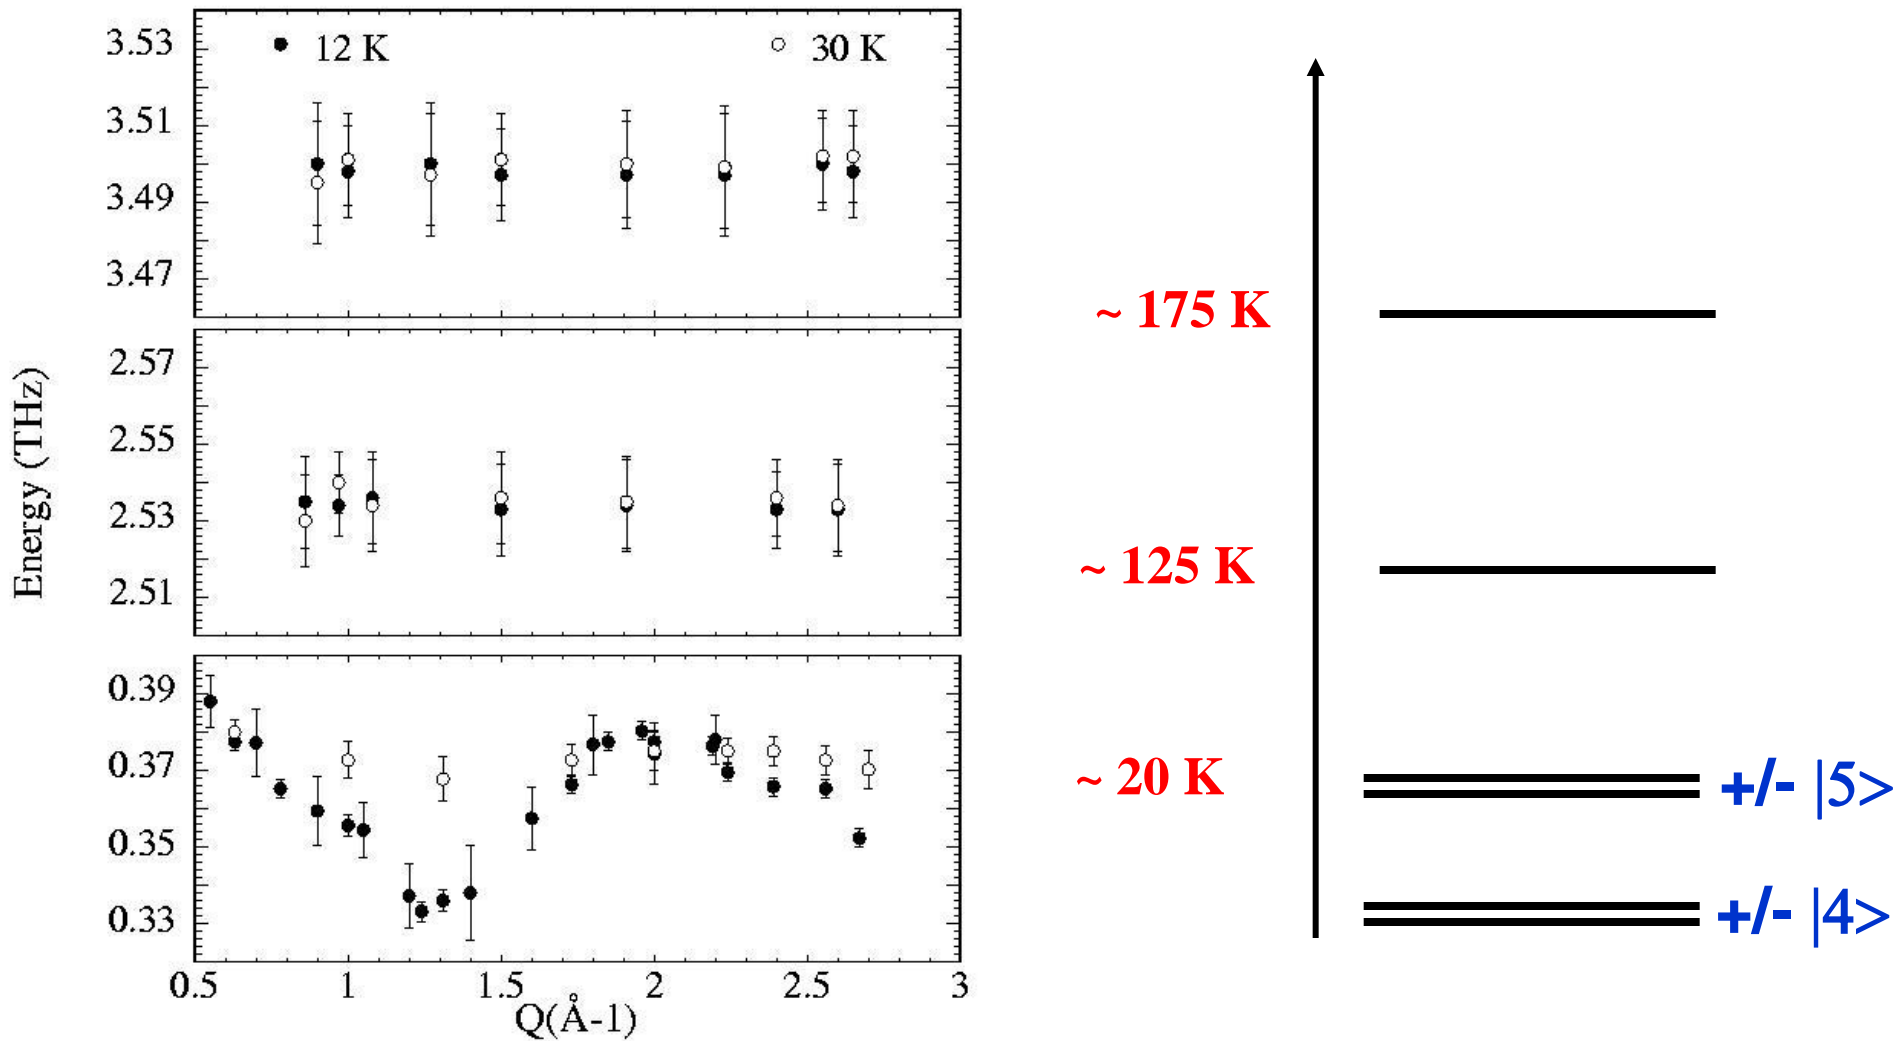

Local Ising anisotropy

Tb^{3+} : $S=3, L=3, J=6$

**$(2J+1) = 13$ states split by the
crystalline electric field**

Inelastic neutron scattering on polycrystalline $\text{Tb}_2\text{Ti}_2\text{O}_7$

(Δ : $\text{Ho}_2\text{Ti}_2\text{O}_7 \sim 240$ K ; $\text{Dy}_2\text{Ti}_2\text{O}_7 \sim 380$ K)

Time-of-flight neutron scattering from DCS on $Tb_2Ti_2O_7$

002 inelastic, $H=0\text{T}$, $T=0.4\text{K}$ 002 inelastic, $H=1\text{T}$, $T=0.4\text{K}$ 002 inelastic, $H=2\text{T}$, $T=0.4\text{K}$ 002 inelastic, $H=3\text{T}$, $T=0.4\text{K}$ 

One Transition in Zero Field

Five Transitions in Non-Zero Field

Conclusions:

- Neutrons probe magnetism on length scales from 1 – 100 Å, and on time scales from 10^{-9} to 10^{-12} seconds
- Magnetic neutron scattering goes like the form factor squared (small κ), follows dipole selection rules $\langle \lambda' | S^{+, -, z} | \lambda \rangle$, and is sensitive only to components of moments \perp to κ .
- Neutron scattering is the most powerful probe of magnetism in materials; magnetism is a killer application of neutron scattering (1 of 3).
